| Abstract Lake Wuliangsuhai is the 8 th largest lake in China and only 170 km ² of 300 km ² is at present considered as open waters due to widespread reed vegetation. The massive pollution loads from domestic, industrial and agricultural sources threatens the existence of the lake. A collaboration project was implemented to study the lake status, trends and threats and to propose Management and Control Plans to secure the lakes existence as a lake. This report provides an overview and results from one of the sub-projects. The sub-project "Water Quality Monitoring System" intends to provide information of the water quality and transport of selected substances in the Hetao Irrigation Area, in the Lake Wuliangsuhai, and its outlet back to Yellow River. This information is important input to an Action Plan for the management of the lake, a permanent monitoring programme, and special surveys to investigate restricted problems, e.g. expected effects of effluents. The water quality is studied in the Hetao Irrigation Area, the main water feeding the lake, as well as in the lake itself and that leaving the lake. |

Inner Mongolia Lake Restoration Project

Sub-Project 3:

Water Quality Monitoring

Final Report

Preface

This is one in a series of reports of the: 'Inner Mongolia Lake Restoration Project'. Inner Mongolia Environmental Science Institute (IMESI) has through the Inner Mongolia Science and Technology Committee and the State Science and Technology Commission applied to Sida and NORAD for financial support to carry out a three years' restoration project in Lake Wuliangsuhan in Inner Mongolia, the Peoples Republic of China.

IVL and NIVA are the consultants of the project.

Water sampling in the lake was carried out by Wulateqianqi Environment Monitoring station (mr. Zhang Fenqing and mr. Zhong Yunfeng) while sampling in the canals was carried out by Bayannour Environment Monitoring station (mr. Ye Junfeng and ms. Guo Yuhua).

Chemical analysis of nutrients and heavy metals from both canals and the lake by Bayannaoer League Monitoring Station in Linhe; other parameters analysed at the lab that is in charge of sampling. Zooplankton and phytoplankton were analysed at the Inner Mongolia Water Production Institute in Hohhot.

Yellow River Management Bureau of Bayannaoer League was the provider of hydrological data and water level data.

Wulateqianqi Meteorological Monitoring Station provided meteorological data and the description of normal climate.

1. CONCLUSIONS AND RECOMMENDATIONS

General conclusions

Lake Wuliangsuhai is a large and shallow lake situated on the Hetao Plain adjacent to the Great Northern Bend of the Yellow River in Inner Mongolia, P.R. China.

The lake is fed mainly by heavily polluted water from The Hetao Irrigation Area originating from discharges from industries and villages and runoff from agriculture. The water quality of the lake is very bad and the concentrations of mineral salts, plant nutrients (P and N) and dissolved organic substances often exceeds the limits of Class V, the worst water quality class in the Chinese water classification system.

50 % of the lake's surface area is today covered with dense reed (mainly *Phragmites australis*), and the remaining 'open water' is filled with submerged vegetation (dominated by *Potamogeton pectinatus*). The lake is therefore classified as a 'grass-type' eutrophicated lake. The reed is utilised as a valuable source of plant fibres for paper production. Efforts have been taken lately to test the use of sun dried *Potamogeton* as feed for sheep, geese and ducks.

The lake formerly had a high production of fish that was the main food item for people in lake-shore 'fishermen villages'. Today small individuals of Golden Carp constitute the main fish catch in the lake. Low winter concentrations of oxygen, and the dense cover of submerged plants, are the major reason why today's fish catches are much smaller and less valuable than before.

Lake Wuliangsuhai supports a large and diverse bird population with both breeding and migrating species, some of which are rare and protected in China.

Water Quality in the tributary canals

For most important parameters (nutrients and organic matter) the water quality is very bad in most drainage canals during the non-irrigation period. This means beyond class V according to Chinese Water Quality Standards. The situation is only slightly better during the irrigation period. The highest concentrations of organic matter were observed in canal 7, whereas canals 3, 5 and 7 had the highest concentrations of nutrients.

The water quality in the three main sources of input water to the lake is characterized by high concentrations of mineral salts, plant nutrients (P and N) and dissolved organic substances. The water quality is very bad in most drainage canals in Hetao; mainly beyond class V according to Chinese

Water Quality Standards. The situation is only slightly better during the irrigation period compared to the non-irrigation period.

The highest concentrations of organic matter were observed in Drainage Canal 7, whereas Drainage Canals 3, 5 and 7 had the highest concentrations of nutrients.

Evapo-transpiration causes considerable increase in mineral salt concentration in water on its way through the Hetao irrigation system. The highest salt concentrations, measured as conductivity, were observed in canals nos. 7, 8 and 9 as well as in the return water into Yellow River downstream the lake. A marked increase (80 %) in conductivity was observed between the Main Pumping Station and the outlet of Lake Wuliangsuhai. This is caused by the high evapo-transpiration from reed and the lake surface.

Pollution loading of the lake and retention in the lake

The estimated loadings of organic matter, total nitrogen and total phosphorus during the investigated period 1999-2002 were:

| | COD (tons/yr) | BOD ₅ (tons/yr) | P (tons/yr) | N (tons/yr) |
|-----------------|---------------|----------------------------|-------------|-------------|
| Into the lake | 10.400-25.800 | 1.000-3.700 | 28-180 | 720-3.600 |
| Out of the lake | 200-12.900 | 5-1.800 | 0,2-38 | 5-590 |

Lake Wuliangsuhai is a sink for nutrients and organic matter and in this way efficiently protects Yellow River from pollution from Hetao Area. A considerable part of the phosphorus, nitrogen and organic matter transported into the lake is retained by adsorption to particles and sedimentation. Also a substantial part of the nitrogen is lost by sedimentation, assimilation by plants and by the denitrification process.

Water Quality in Lake Wuliangsuhai

The discharge of organic matter into Lake Wuliangsuhai from the Hetao area is so large that the concentration of these variables are beyond the classification standard (exceed class V), when measured as BOD₅ and COD. Only in the southern part of Lake Wuliangsuhai, at the central Erdiar station, the organic content is within the limits of class V during summer. For Total nitrogen the water quality class is beyond class V at both lake stations, except at Erdiar during winter (class V). A large part of the Total nitrogen is present as ammonium. Total phosphorus is in class V the whole year around in the southern basin, while in the northern basin, at Xidatian, it is beyond class V in winter and in class IV-V during the rest of the year.

The water quality is generally much worse in the Xidatian basin close to the Main Pumping Station than in other parts of the lake. The dense reed stands surrounding the Xidatian and the Potamogeton in the lake reduces the impact of the high pollution loading from Hetao Area. However, in the non-irrigation period the concentrations of dissolved organic matter were higher in the southern part than in the northern part. Annual average values of pH are in the range 8-9 due to the high plant production.

Annual average values for metals, arsenic and cyanide are within Classes I-III according to the Chinese Water Quality Standards, for both lake sampling stations. However, Mercury and Chromium were up to class IV some years. Generally the concentrations were higher at Xidatian than at Erdiar.

Concentrations of Chromium were also quite high at the main pumping station, especially in the year 2000 (Class V). The concentrations of Cadmium, Chromium, Arsenic and Cyanide were low or moderately high at other canal stations (class I-IV). There was a marked increase in concentration of several metals between the outlet of the lake and the inlet into Yellow River caused by effluents from industries in the Wulateqianqi area. Here the mean values of Chromium and Arsenic exceeded class V some years.

Macrophytes and plankton

Large parts of the shallow areas of Lake Wuliangsuhai are covered with reed, primarily *Phragmites australis* and *Typha* spp. The maximum depth at the lakeward edge of the reed is found to be ca. 1.2 m. It seems that the lake depth is a critical factor for further expansion of the reed.

The by far most dominating species of submerged vegetation is *Potamogeton pectinatus*. Also a number of other species of the genera *Ceratophyllum* and *Chara* are abundant. Only in the deepest areas of "open water" are the bottom not covered with submerged vegetation.

Submerged vegetation covers a major part of the lake bottom between 1.0 and 2.0 m depth. Below 2.5 meters most observations were without plants.

The phytoplankton biomass enumeration shows high biomasses characteristic for highly eutrophic lake conditions. It must be stressed that the conversion factors from phytoplankton numbers to biomass are questionable and that this may have led to an overestimation of biomass. A considerable part of the phytoplankton algae, especially the diatoms, probably arises from resuspension from the bottom or from the submerged vegetation.

The characteristics of the zooplankton in Lake Wuliangsuhai are the high numbers of Rotifera species and the high biomass of Copepoda, whereas Cladocera is only observed at low concentrations.

Fish

Total fish catches in Lake Wuliangsuhai have varied in the range 300-3600 tons per year since 1960. In the period 1960-1974 there was a dramatic decline in total commercial fish catches. From the late 1970s to the late 1990s the fish catches have varied from low to medium level compared to the early 1960s. After prohibition of fishing in 2000 and 2001, the total catches in 2002 reached a level comparable to that in the early 1960s. However, in 2003 there was a decrease of about 50% compared to the previous year. In later years the catches have been totally dominated by small sized Golden Carp.

Maintenance of the fish population in the lake has been strongly supported by annual introductions of young individuals of different fish species.

Reduced loading of dissolved organic substances and plant nutrients combined with excavation of some deeper areas without submerged vegetation would support the development of a larger standing crop of fish consisting of bigger individuals, due to better winter survival conditions. When the environmental conditions have been improved, introduction of other, more valuable fish species should be considered. However, their possible negative impacts upon the lake ecosystem, e.g. on submerged vegetation, turbidity, other fish species, should be carefully considered.

Development of water quality over time

During the last 15-20 years the water quality of Lake Wuliangsuhai has become severely deteriorated. For example, total phosphorus concentrations have increased from class IV to class V, and total nitrogen concentrations have increased from class IV to beyond class V according to the Chinese water quality standards. Average summer pH has shown a significant increase during the same period, probably because of increasing plant production. Winter kills of fish because of anoxic water have become common, and there has been a 60% reduction in the number of fish species. The total number of zooplankton species has also been significantly reduced during this period.

If comprehensive measures are not taken to reduce the pollution inputs to the lake, and maintain at least the present input of water, the water quality will become even worse than today. Winter kills of fish will continue to occur regularly and the biodiversity of fish, zooplankton and birds will be further reduced. Reduced water input and a lower water level are possible additional threats to the lake. The high sedimentation rate because of large inputs of organic matter and particles as well as high internal production of plant material implies that the lake will tend to become a marsh wetland within few decades.

Large scale loss or removal of submerged plants of the lake should be carefully avoided, as it

may initiate heavy blooms of phytoplankton in the lake, probably blue-greens with a potential for toxin production.

Birds

Lake Wuliangsuhai is important for a large number of bird species, both as a breeding area and a stop-over on the migration to and from breeding areas further to the north. The low availability of freshwater wetlands and lakes in this dry region of China gives Lake Wuliangsuhai a high importance for the bird migration in North Eastern parts of Asia. According to the data from 1996, 181 species of birds were recorded in the wetland of Wuliangsuhai. Among these, 5 species belong to the first order of rare birds protected by the state, and 25 species belong to the second order of rare birds protected by the state. During the surveys in September 2000 and April 2004 more than 18,000 and 53,000 bird individuals were observed respectively. In total 128 bird species were identified during these two surveys. Of these, 11 and 9 species not previously reported from the lake were identified in 2000 and 2004, respectively. After these investigations the number of observed bird species has reached a total of 208.

The lake attracts a large number of bird individuals and species. Restoration measures should therefore be evaluated carefully with respect to intended and unintended effects on the bird fauna. Different restoration measures and other human activities may affect the number and species composition of breeding and migrating birds. Lake Wuliangsuhai fulfils the criteria to become an internationally protected area according to the RAMSAR convention, and an application to the convention would probably be an important tool to protect the bird life and the habitat diversity of the lake.

Water evaporation and management

Although the inputs of water into Lake Wuliangsuhai vary considerably between years, the loss by evapo-transpiration and percolation to the groundwater from the lake is relatively constant at ca. $400 \times 10^6 \text{ m}^3/\text{yr}$. This implies that the minimum annual water input from canals cannot go below this value without gradually reducing the water level on an annual basis. A lower water level than today might cause a rapid expansion of reed further into ‘open water’ areas of the lake. In addition, timing of the water inputs must be considered together with regulation regime of the outlet dam, not to reduce the water level below accepted levels. The annual mean water level of Lake Wuliangsuhai has varied in the range 1018.4-1018.9 m with an average of 1018.5 m above sea level in later years.

1 INTRODUCTION

Aim of this sub-project

The purpose of the sub-project 3: Water Quality Monitoring System is to provide information of the water quality and transport of selected substances in the Hetao Irrigation Area, in the Lake Wuliangsuhan, and its outlet back to Yellow River. This information is important input to an Action Plan for the management of the lake, a permanent monitoring programme, and special surveys to investigate restricted problems, e.g. expected effects of effluents.

The water quality is studied in the Hetao Irrigation Area, the main water feeding the lake, as well as in the lake itself and that leaving the lake.

2 METHODS

The "Water Quality Monitoring" sub-project has been carried out by performing different methods:

- Monitoring of water quality and pollution transport in canals of the Hetao Irrigation System
- Monitoring of water quality in Lake Wuliangsuhai
- Collection of relevant monitoring data from canals and the lake prior to this project
- Collection of data of annual fish harvest and introduction of fish
- Performing test-fishing
- Estimating rough hydrological budget for Hetao Irrigation System upstream the lake
- Estimating rough hydrological budget of Lake Wuliangsuhai
- Carrying out bird surveys in spring and autumn

2.1 Canals Monitoring

2.1.1 Sampling Stations

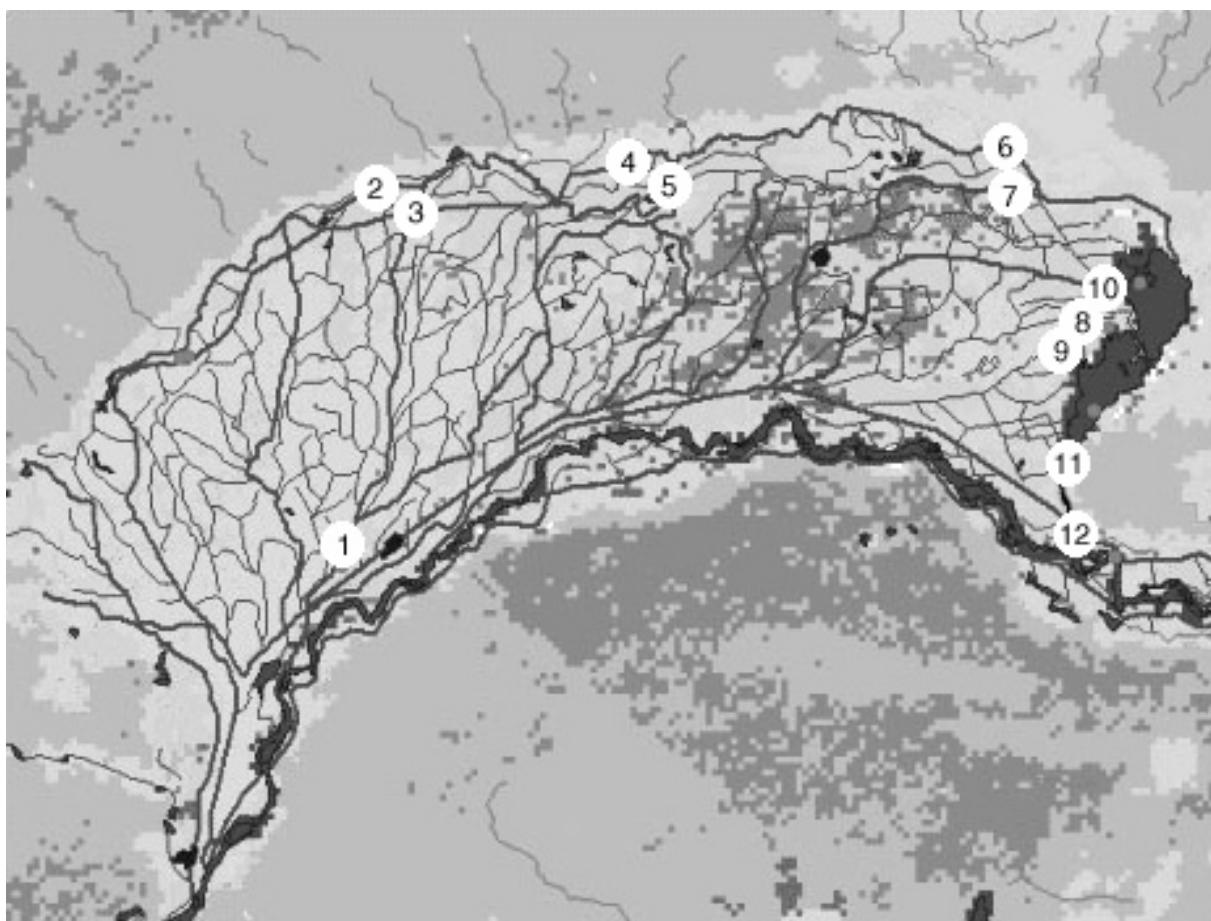

Figure 3.1 Map of Hetao with canal sampling stations. Numbers are according to table below.

Sampling of water samples was carried out in a total of 12 canal stations according to the map above. Many of these stations have been part of the previously running monitoring programme of the Hetao area. The sampling station no. 1 was established in 2001 to monitor the water quality in Yellow River water in the Main Irrigation Canal. 4 stations along the Main Drainage Canal (2, 4, 6 and 10) will be used to record the changes in water quality along this canal. Station 10 (Main Pumping Station) is the major water input to Lake Wuliangsuhai, whereas stations 8 and 9 carry the remaining load of water from Hetao to the lake. Precipitation water from the mountains to the north and east of the lake is not measured in this investigation, but its volume is considered normally low and the water is not polluted. Two stations have been sampled in the outlet canal of the lake: one near the outlet dam and one just before it runs into Yellow River. The last station will include pollution from the village Wulateqianqi and its factories.

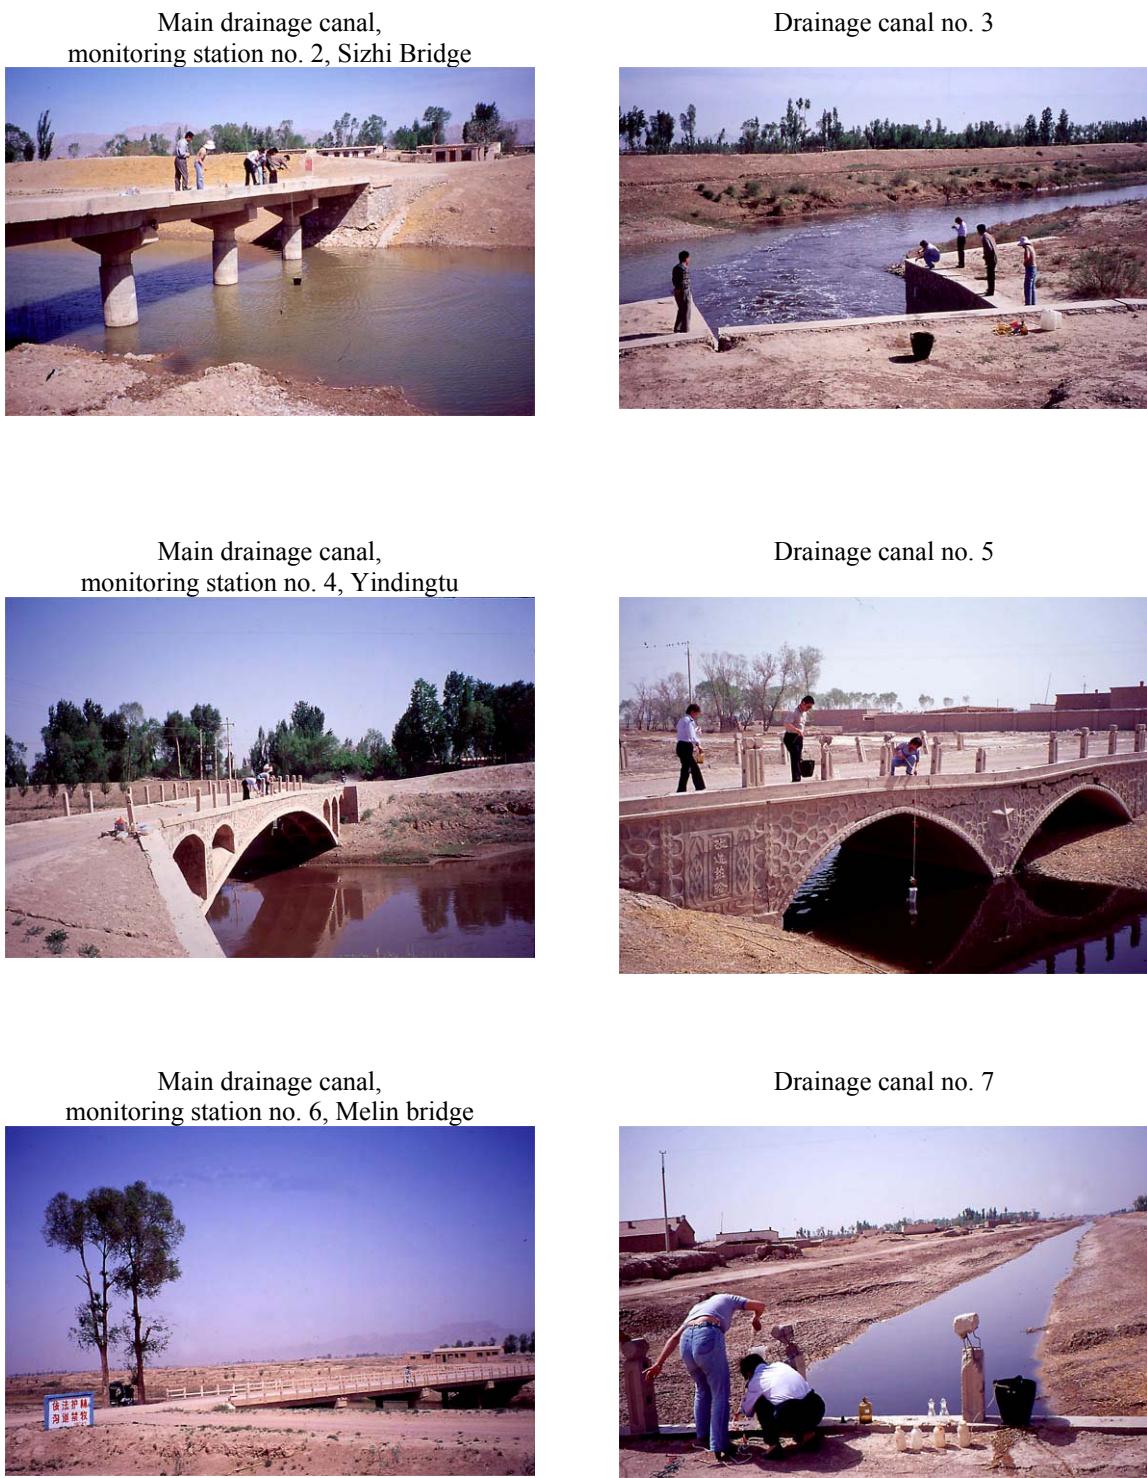

Figure 3.2 Photos of canal monitoring stations nos. 2-7 (Photos: Tone Jørn Oredalen)

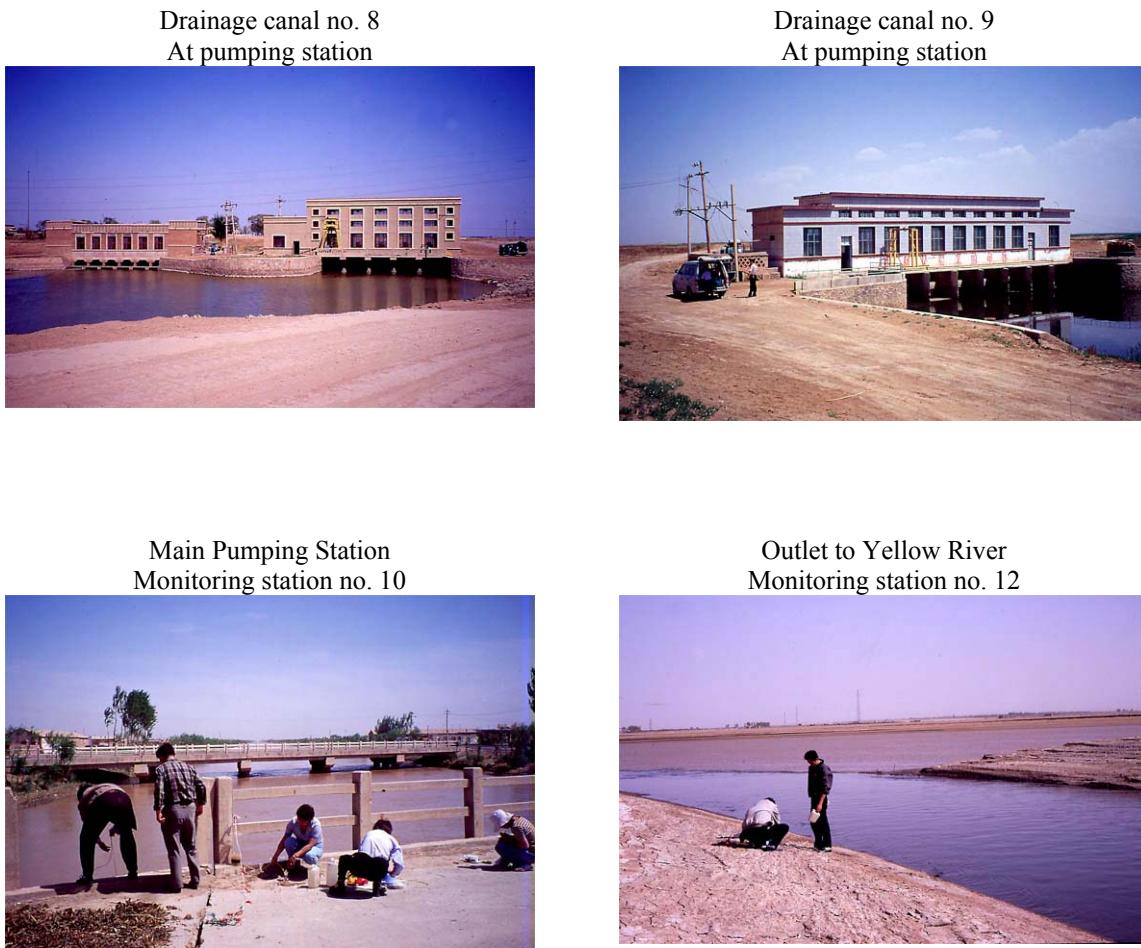

Figure 3.3 Photos of canal monitoring stations nos. 8-12 (Photos: Tone Jørn Oredalen and Bjørn Faafeng, nr.11)

2.1.2 Water sampling in the canals

Sampling frequency

Each station was sampled 2-10 times a year, most frequently in irrigation periods. The highest number of samples was collected in 2001; 1 sampling in February, then monthly from April to December.

The following variables were analysed:

- Major chemical constituents (Na, K, Ca, Mg, Cl, SO₄, alkalinity, HCO₃⁻, CO₃²⁻)
- pH, conductivity, oxygen, water colour
- Nitrogen (total-N, nitrate, nitrite, ammonium)
- Phosphorus (total-P, filtrated PO₄-P)
- Oxygen concentration.

The sample bottles were transported to the laboratory in cool boxes the same day as they were collected.

2.1.3 Water Flow Measurement

For drainage canals

The discharge of the drainage canals is measured by water flow meters 2 times every day, during daytime and night. Water flow is calculated by multiplying the area of the section of the canals by water speed.

Main drainage canal

The discharge of the drainage canal is measured by speed meter every day, 2 times per day, during daytime and night, and at the meantime, measuring the height of the water in the canal. Water flow is calculated by multiplying the area of the section by water speed.

2.1.4 Water Analysis

Table 3.2 Methods of water analysis and detection limits. Chemical analyses were performed according to Chinese Monitoring Standards.

| Analytical item | Analytical method | Detection limits |
|-------------------------------|--------------------------------------|------------------|
| pH | Electrometry | - |
| COD _{Cr} | Titrimetric | 5 mg/l |
| COD _{Mn} | Titrimetric | 0.2 mg/l |
| NH ₃ -N | Photometry | 0.025 mg/l |
| NO ₃ -N | Photometry | 0.02 mg/l |
| NO ₂ -N | Photometry | 0.003 mg/l |
| Tot-P | Photometry | 0.01 mg/l |
| Cr ⁶⁺ | Photometry | 0.004 mg/l |
| Hg | Cold atomic absorption spectrometer | 0.00005 mg/l |
| PO ₄ -P | Photometry | 0.01 mg/l |
| CN ⁻ | Photometry | 0.004 mg/l |
| Tot-N | Photometry | 0.05 mg/l |
| Cl ⁻ | Titrimetric with AgNO ₃ | 10 mg/l |
| As | Polarography | 0.001 mg/l |
| Pb | Voltammetry | 0.001 mg/l |
| Cd | Voltammetry | 0.0005 mg/l |
| Cu | Flame atomic absorption spectrometer | 0.05 mg/l |
| Zn | Flame atomic absorption spectrometer | 0.05 mg/l |
| K | Flame atomic absorption spectrometer | 0.03 mg/l |
| Na | Flame atomic absorption spectrometer | 0.01 mg/l |
| Ca | Titrimetric, EDTA | 0.5 mg/l |
| Mg | Titrimetric, EDTA | 0.5 mg/l |
| Fe | Flame atomic absorption spectrometer | 0.03 mg/l |
| Mn | Flame atomic absorption spectrometer | 0.01 mg/l |
| HCO ₃ ⁻ | Titrimetric | 0.5 mg/l |
| CO ₃ ²⁻ | Titrimetric | 0.5 mg/l |
| SO ₄ ²⁻ | Photometry | 8 mg/l |
| SS | Gravimetry | 0.2 mg/l |
| BOD ₅ | Incubator 20 °C, Titrimetric | 2 mg/l |
| DO | Titrimetric | 0.2 mg/l |

Some of the chemical (spectrophotometric) analyses from the Main Irrigation Canal, which represents the water quality of the Yellow River, are probably misleading. It is likely that the

values of for instance Tot P and Tot N are generally too high because of interference with particles in the Yellow River water, which is very turbid.

2.1.5 Calculation of Pollutants Transport

Time-weighted flow

The calculation of mass transport of different substances is based on time-weighted average values of concentrations and the amounts of water transported in that certain period;

$$S = C * V \quad \text{where}$$

S = Mass transport (tons)

C = Average concentration (mg/L)

V = Water transport in period (mill. m³)

Time weighted concentrations (C) is defined as:

C = Sum (C_i*t_i)/Sum t_i, where C_i is the average concentration between two following samplings and t_i is the number of days between the two sampling dates.

For a selected number of parameters (see Table below) time-weighted transports are calculated. For a year with both monthly concentrations and monthly flow values, monthly flows are calculated. When this is not the case, available concentration values have been assumed representative also for preceding and/or following months. In some years only a few measurements were done during the irrigation period. However, in 2001 monthly measurements were carried out from May to October.

For the Main Pumping Station flow data is missing for 1997. Due to lacking other information, the arithmetic mean of preceding and following year's values for each month is used.

The transport values have been calculated for a selection of parameters for the monitoring points given in the tables below.

Table 3.3 Parameters included in the transport calculations

COD

BOD₅

Total P

Total N

Table 3.4 Transport calculations are performed on the following monitoring points where water flow and concentration of substances have been measured

Site Name

Main Pumping Station

Outlet of Lake Wuliangsuhai

In order to estimate the total annual transport in the canals of the most important substances measured, the calculations should have been split into two seasons: the irrigation period and the non-irrigation period. This is due to the considerable differences in water flow in the drainage canals during these periods. In the irrigation period the pollution from point sources are diluted by irrigation water and seepage from the farmland, whereas in the non-irrigation period the dilution is much smaller, and hence the concentration of pollutants is much higher. Here transport calculations are only performed for the irrigation period, due to very few concentration measurements which would have introduced large uncertainties in the calculations.

The irrigation period is roughly between early April and the end of October. However, the water flow in the drainage canals is still decreasing, but considerable in November according to the tables in Appendix. This has led us to carry out the calculations for two alternative irrigation seasons: April – November and April – December, respectively.

For a selected number of parameters (Table 3.3) time-weighted transports are calculated. For a year with both monthly concentrations and monthly flow values, monthly flows are calculated. When this is not the case, available concentration values have been assumed representative also for preceding and/or following months.

The Main Pumping Station is missing flow data for 1997. Lacking other information, the arithmetic mean of preceding and following year's values for each month is used.

2.1.6 Chinese Water Quality Standards

Table 3.5 The Chinese Water Quality Standards for relevant parameters in rivers and lakes (mg/L except pH).

| 1. Rivers and lakes | Class I | Class II | Class III | Class IV | Class V |
|----------------------------|----------------|-----------------|------------------|-----------------|----------------|
| pH | | ----- | 6 – 9 | ----- | |
| DO | ≥ 90% (7,5) | | 6 | 5 | 3 |
| COD _{Mn} | ≤ 2 | 4 | 6 | 10 | 15 |
| COD _{Cr} | ≤ 15 | 15 | 20 | 30 | 40 |
| BOD ₅ | ≤ 3 | 3 | 4 | 6 | 10 |
| NH ₃ -N | ≤ 0,15 | 0,5 | 1,0 | 1,5 | 2,0 |
| TP (rivers) | ≤ 0,02 | 0,1 | 0,2 | 0,3 | 0,4 |
| TP, (lakes) | ≤ 0,01 | 0,025 | 0,05 | 0,1 | 0,2 |
| TN | ≤ 0,2 | 0,5 | 1,0 | 1,5 | 2,0 |
| Cu | ≤ 0,01 | 1,0 | 1,0 | 1,0 | 1,0 |
| Zn | ≤ 0,05 | 1,0 | 1,0 | 2,0 | 2,0 |
| As | ≤ 0,05 | 0,05 | 0,05 | 0,1 | 0,1 |
| Hg | ≤ 0,00005 | 0,00005 | 0,0001 | 0,001 | 0,001 |

| Pb | ≤ 0,01 | 0,01 | 0,05 | 0,05 | 0,1 |
| CN ⁻ | ≤ 0,005 | 0,05 | 0,2 | 0,2 | 0,2 |
| Hydroxybenzene | ≤ 0,002 | 0,002 | 0,005 | 0,01 | 0,01 |
| Oil | ≤ 0,05 | 0,05 | 0,05 | 0,5 | 1,0 |

Table 3.6 The Chinese Water Quality Standards for relevant parameters in drinking water.

| 2. Drinking water (mg/L) | | |
|---------------------------------|-------------------------------|----------|
| | Items | Standard |
| 1 | SO ₄ ²⁻ | 250 |
| 2 | Cl ⁻ | 250 |
| 3 | NO ₃ ²⁻ | 10 |
| 4 | Fe | 0,3 |
| 5 | Mn | 0,1 |

2.2 Lake Monitoring

2.2.1 Lake water level

The lake water level was measured by manual readings on a ruler fixed to the bottom near the outlet of the lake. Observations were done twice each day; at 8 a clock in the morning and 8 a clock in the evening. The averages of these two reading are the daily water level values, expressed as height (m) above sea level.

2.2.2 Sampling stations

Two sampling stations were used in Lake Wuliangsuhan; one close to the Main Pumping Station: Station North (*Xidatian*). At this station the water quality is heavily affected by the polluted water from the Main Drainage canal (st.10). The other was in the deepest area in the main basin: Station South (*Erdiar*).

Table 3.7 Co-ordinates for the lake's monitoring stations

| | North | East |
|--------------------------|------------|-------------|
| Xidatian (Station North) | 41° 00,189 | 108° 52,010 |
| Erdiar (Station South) | 40° 49,905 | 108° 45,282 |

The map has been constructed from a satellite image from 2001 (see report on Historical Development)

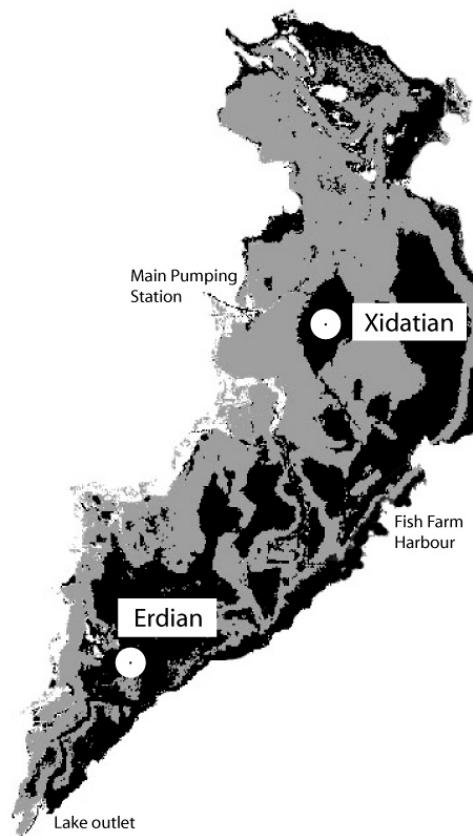

Figure 3.4 The two sampling stations in Lake Wuliangsuhai: Xidatian (close to outlet of Main Pumping Station) and Erdian (deepest point of lake in southern basin).

2.2.3 Sampling and analysis of Water, Plankton and Sediment

2.2.3.1 Water chemistry samples

Sampling frequency

Each station is sampled 2-10 times a year, most frequently in the ice free season. The highest number of samples was collected in 2001; 1 sampling in February, then monthly from April to October and 1 sampling in December.

Sampling procedure

A cylindrical open-top type 3.5 L Limnos water sampler was used for the water chemistry samples. The sampler can be closed with a messenger at the sample depths.

All field data (date, sampling depths, weather conditions and personnel) were noted in a field notebook.

The following variables were analysed:

- Major chemical constituents (Na, K, Ca, Mg, Cl, SO₄, alkalinity, HCO₃⁻, CO₃²⁻)
- pH, conductivity, oxygen, water colour
- Nitrogen (total-N, nitrate, nitrite, ammonium)
- Phosphorus (total-P, filtrated PO₄-P)
- Oxygen concentration (every 0.3 meter from surface to bottom).

The sample bottles were transported to the laboratory in cool boxes the same day as they were collected.

The monitoring program should also include observations on Secchi disc transparency. Unfortunately this has not been carried out.

2.2.3.2 Plankton samples

Phytoplankton

Phytoplankton was sampled both qualitatively and quantitatively. The qualitative samples were only used for identifications. They were collected by using plankton net with a mesh size of 25 µm and 30 cm diameter circular opening. The plankton net was pulled slowly horizontally after the boat. The quantitative samples were collected by use of the 3.5 L Limnos sampler making a 2.5 L mixed sample out of 2-3 single samples from the surface, medium depth and approximately 0.5 m above the bottom. 1.0 L of the mix samples were fixed for analyses. Both net samples and volume samples were fixed with 4% formalin or Lugol's solution.

For the quantitative analyses, 1.0 L was concentrated to 30-50 ml in a sedimentation chamber, and out of that 0.1 ml was used for identifying and counting the numbers of phytoplankton cells. Standard specific individual wet weights were used when calculating the biomasses. As the identifications only were done to genera and not to species, there are quite large uncertainties in the calculated biomasses.

Zooplankton

Qualitative samples of zooplankton were collected by using the plankton net (No 13) and pulling it slowly horizontally after the boat for about 5 minutes. The quantitative zooplankton samples were collected by using the Limnos water sampler and making 10 L mixed samples. Each mixed sample was concentrated through the plankton net to approximately 1.0 L that was used for the analyses. The zooplankton samples were fixed by formalin or sometimes with Lugol's solution. The samples were concentrated to 10-15 ml out of which 1 ml was used for counting of large species and 0.1 ml was used for counting of small species. Two parallels were analyzed and the averages were used for the calculations. Standard specific individual wet weights were used when calculating the biomasses.

2.2.3.3 Sediment

Sediment samples were collected at the lake station Erdiar in June 2001 and April 2002 and at both lake stations in January 2002. An open barrel gravity corer was used to collect the sediment samples. These were sliced into 7-30 different 2.5 cm or 5 cm thick layers from the top to the bottom of the core in the field and later analyzed for water content, organic matter (loss of ignition) and the following heavy metals and nutrients: As, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, V, Zn, Total N, Total P and PO₄-P.

Accurate analyses of sedimentation rates were not possible to perform, since the necessary equipment was not available in Hohehot. However, a rough calculation of the sedimentation rate was possible to do on the basis of the distance between the sediment top and the inorganic sandy sediments which probably were deposited before the lake was separated from the Yellow river.

2.2.4 Maximum growth depth of reed and submerged vegetation

The water depth was measured in the open water along the edge of the reed belts in central parts of the lake to have a picture of the maximum growth depth of the *Phragmites* and *Typha* vegetation. GPS co-ordinates were measured simultaneously to allow identification of the different measuring points.

Depths were adjusted to represent average annual lake levels (1018.5 m).

2.2.5 Fish

2.2.5.1 Test-fishing

Test-fishing was carried out at three different stations near Erdiar and Xidatian monitoring sites of the lake with gill nets of different mesh-size (20, 20, 24, 29, 33, 36 mm). The gill nets used were each about 25 m long and 1.5 m high with floaters in the upper end and lead weights in the lower end. Methods of the test-fishing are to set the nets in the evening and leave them through the night and then to pick them up the next morning. All fishes in each net were identified to species and their sizes measured. We also sampled scales and ear-stone (otoliths) from some fishes to confirm their ages, but these have not yet been analysed.

2.2.5.2 Fish catch statistics

Commercial fish catch statistics was provided by the Lake Production Company (Fish Farm) of Lake Wuliangsuhai. This organisation has divided the fishermen into several production groups. Each group has their own part of the lake for fishing. The fishermen mainly fish in the part of the lake that is appointed to them. Twice a year (June/July and October/November) fish catch statistics data are delivered from each of these fishermen groups to the Fish Farm. The catch data are presented for each fish species. The sum of the data for all groups and the two data sets each year is the total yearly fish catch.

Most of the small fish caught in the lake is sold as feed for fish-farming.

2.2.5.3 Annual fish introductions

At the end of September and the beginning of October, juvenile fish were transported to Lake Wuliangsuhai, and introduced to the lake by boats on the site of Nan Tianmeng. The annual number of introduced fish was about 500.000, and in total 12.500 kg (average weight 25 g) at a cost of 140.000 RMB. Statistics have been given by the Lake Production Company (Fish Farm) of Lake Wuliangsuhai.

2.3 Birds

A separate report from a bird survey in Lake Wuliangsuhai during September 2000 has been produced by Anders Svendson at IVL (*A. Svenson, 2000. Survey of autumn migration of birds at Lake Wuliangsuhai, Inner Mongolia, P.R. China. 51 pp.*) During April 17 to April 28 2004 a spring survey of bird observations was also carried out (*A. Svenson et al. 2004. Inventory of spring migration of birds at Lake Wuliangsuhai, Inner Mongolia, P.R. China, in MS*). This report will also include assessments on effects on the avifauna of the present use of the lake, as well as suggestions on management measures to protect bird life and maintain a variety of habitats in the lake. The methods and results from these two surveys are described in detail in these reports, and only a short summary will be given here.

Migrating birds were observed on suitable sites along the eastern lake shore during September 11 to 19 2000. In 2004 too a number of localities on the eastern shore of the lake were visited. The island Nan Tianmen was visited as well. Birds were identified and counted by using a 10 x 40 binocular and a 27 x 60 telescope fitted to a tripod. A micro cassette recorder was used to take up primary field notes. The observation sites were located using a Garmin GPS.

3 RESULTS

3.4 Climate

The climate in the area is of the dry, continental type.

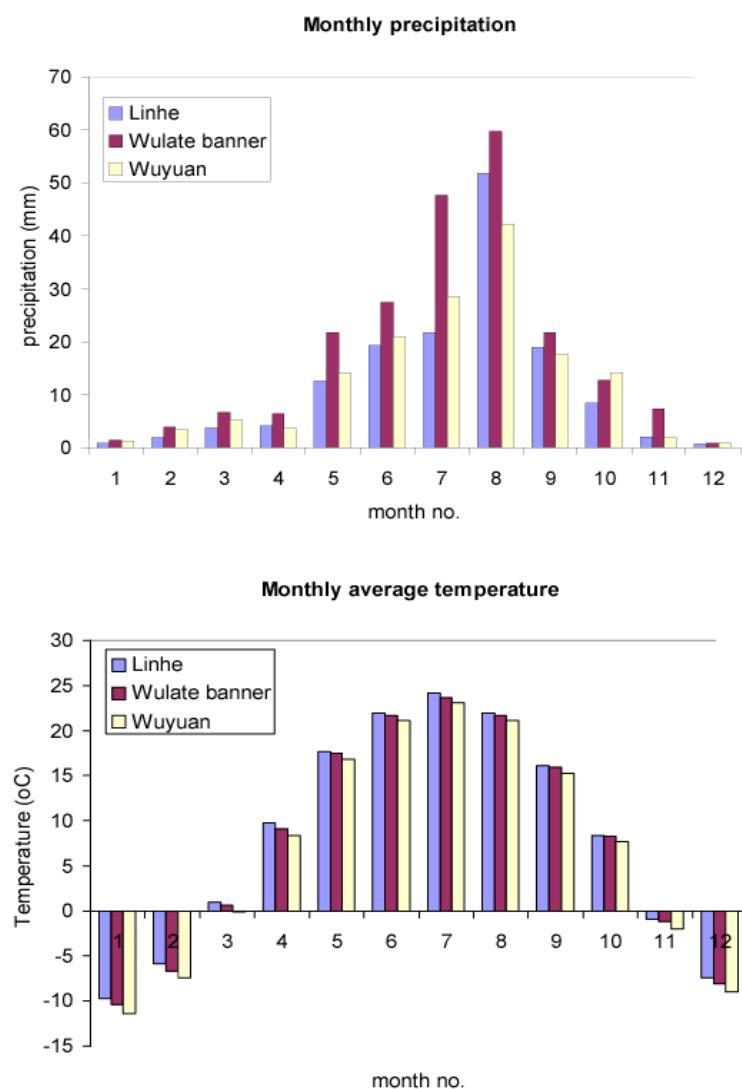

Figure 4.1 Normal average values of precipitation and monthly temperature for 3 stations in the Hetao area: Linhe, Wulateqianqi and Wuyuan.

Temperature

The annual average temperature in the area is 6-8 °C, with the lowest temperatures in January, and the highest in July. The average frost period over many years is 134-150 days, starting during the last ten days of September and ending during the first ten days of April. The annual air humidity is within 50-60 %.

Precipitation

The average rainfall over many years is within 130-215 mm, increasing from the west to the east and concentrating in the July and August. Rainfall exceeding 15 mm is normally restricted to 5-10 days per year.

Evaporation capacity

The evaporation capacity is beyond 2,100-2,400 mm/yr, increasing from the east to the west. The largest portion is measured from April to June, being 40 % of it.

Wind

The wind is strong and frequent in this area and westerly and north-westerly winds prevail. The windiest seasons are in the spring and winter. The wind is stronger in the winter, but lasts longer in the spring. The monthly average maximum wind speed is 19.6 m/s. The number of sand storm days is 47-105.

3.5 Water Flow In The Hetao Canal System

3.5.1 How the Water Flow is regulated

The key water conservancy project of Yellow River at Sanshenggong, Denkuo was completed in 1961. A sluice gate of the Main Irrigation Canal was built to divert water from Yellow River into the Hetao Area. This gate is open during the irrigation period, i.e. the irrigation period is restricted to mid April to late October. During this period half of the water flow of Yellow River at this point is diverted into Hetao for irrigation purposes.

The total Hetao Irrigation Area uses the irrigation water diverted from the main canal by gravity flow. A few of the sub-slue gates were constructed on the Main Irrigation Canal in order to raise the water level and to allow diverting from this canal by gravity flow. The canal system of the Hetao Irrigation System consists of 7 levels of canals:

1. the main irrigation canal (parallel to Yellow River)
2. canal
3. sub-canal
4. branch canal
5. lateral canal
6. sub-lateral canal and
7. field ditch.

The irrigation water is distributed from upper level canals to lower ones and finally enters the farm fields through the field ditch. On each level the water flow can be controlled by a hand operated sluice gate.

Figure 4.8 Typical gate for regulating water flow into the farmland. Photo: Hans Ljungquist, Global School

On the downstream side of the farmland, the drainage canal system also consists of 7 levels. After irrigation of the farm fields, some of the surplus water permeating the ground discharges into the drainage field ditch, and then into drainage sub-lateral canals, drainage lateral canals, and so on. In the end, the drainage water enters the Main Drainage Canal, which runs parallel to the Main Irrigation canal about 200 km further to the north, and finally into Lake Wuliangsuhai through The Main Pumping Station. Only drainage water from Drainage canals 8 and 9 are pumped directly into the lake via separate pumping stations.

The water in Lake Wuliangsuhai discharges into Yellow River by gravity flow. A dam regulates the water level of Lake Wuliangsuhai according to the need for flood protection, a stable water level through the winter etc. The lake occasionally receives backwash water from Yellow River via the outflow canal. In this way the lake may serve as a flood protection reservoir for the lower parts of Yellow River.

3.5.2 Water diversion from Yellow River at Sanshenggong

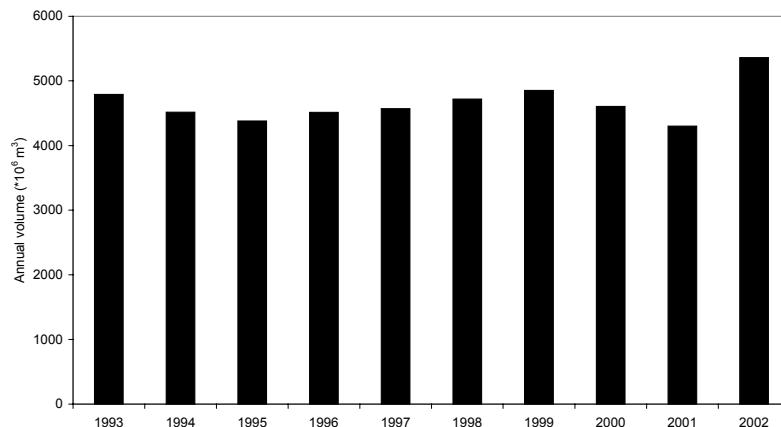

The amount of water diverted from Yellow River into Hetao Irrigation Area is presented in the table below. Average monthly and annual values for the period 1993 and 2002 are also given.

Table 4.1 Diverted water volume from yellow river into the Hetao Irrigation Area

Waterflow Sansenggong into Hetao Area (unit: 10^6 m^3)

| month/year | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | Average |

| Desember | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 | 0,0 |
| yearly total: | 4791,4 | 4517,5 | 4379,8 | 4515,2 | 4569,1 | 4719,2 | 4853,1 | 4605,3 | 4302,4 | 5361,5 | 4661,5 |

The annual irrigation volume varied little during the period 1993 to 2002 with an average value of $4,661 \times 10^9 \text{ m}^3$.

*Figure 4.9 Annual water diversion volumes at Sanshenggong 1993-2002 (*10⁶ m³)*

The irrigation period is restricted to mid April to late October. Due to the irrigation cycle there are two distinct irrigation periods; one from April to July, the other from mid September to late October as shown in the graph below. This affects the water flow both in irrigation and drainage canals.

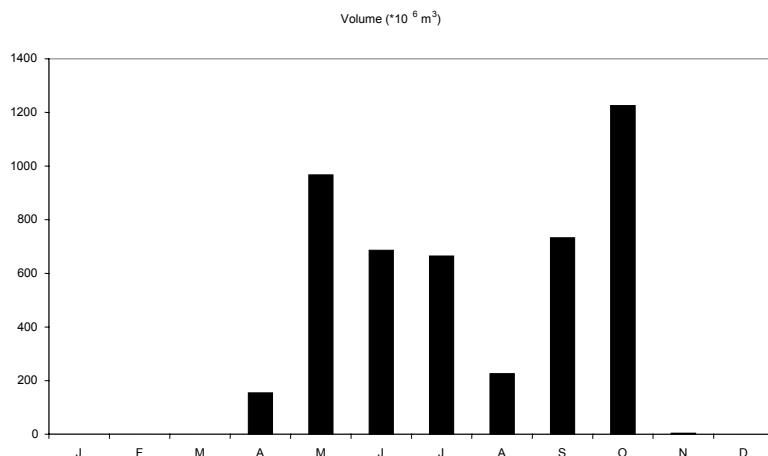

Figure 4.10 Average monthly diversion volumes at Sanshenggong 1993-2002

3.5.3 Water flow in drainage Canals 1999 - 2002

This investigation has been restricted to those canals with the expected highest importance for pollution transport and water flow; e.g. canals numbers: 3, 5, 7, 8 and 9, 4 stations in the Main Drainage Canal and in addition 2 stations in the outlet canal from the lake back to Yellow River. The following section presents the water flow in these canals during the years 1995 - 2002.

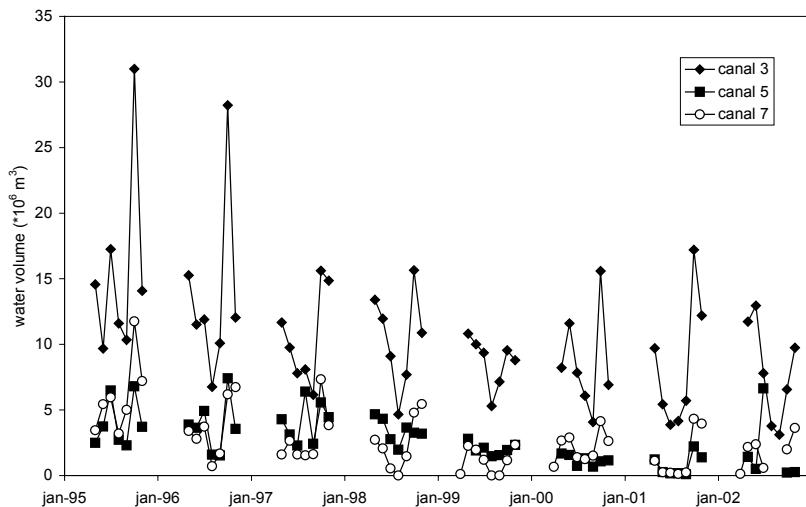

Figure 4.11 Monthly water volumes 1995 - 2002 at canals nos. 3, 5 and 7

In 2002 surplus water was taken from Yellow River to flush the lake.

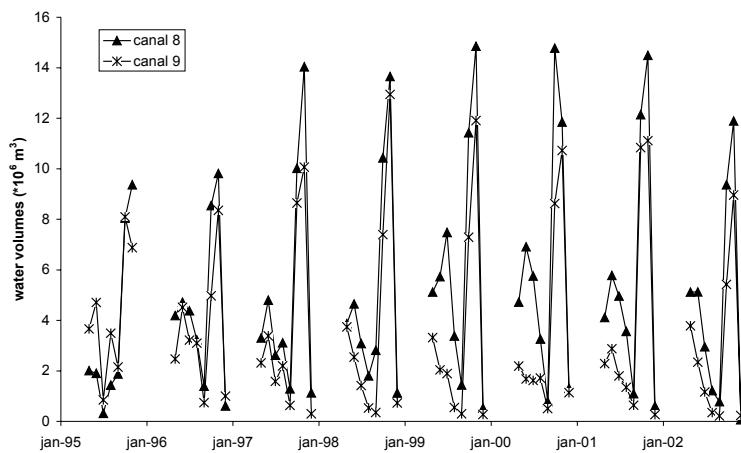

Figure 4.12 Monthly water volumes 1995 - 2002 at canals nos. 8 and 9

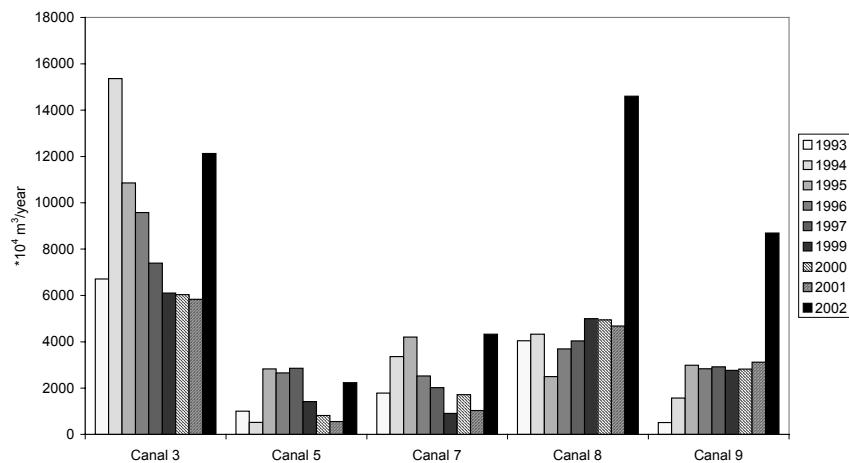

Figure 4.13 The annual water flow in canals nos. 3, 5, 7, 8 and 9 during 1993 - 2002

3.5.4 Rough Water Balance of the Hetao Irrigation Area

A simplified hydrological budget for the Hetao Irrigation Area can be established with 3 main inputs (irrigation water from Yellow River, input from mountains and from precipitation directly on the irrigation area) and 3 losses (direct outlet to Yellow River, outlet to Lake Wuliangsuhai via drainage canals and evapotranspiration):

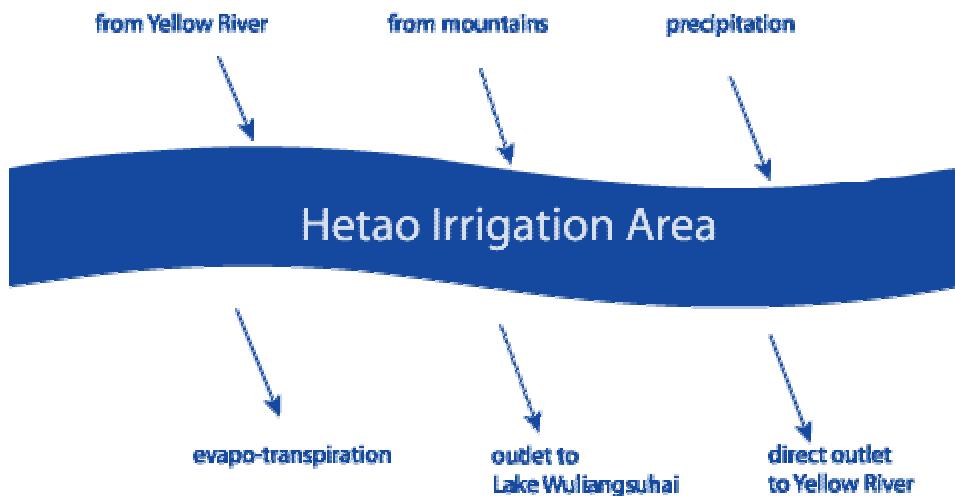

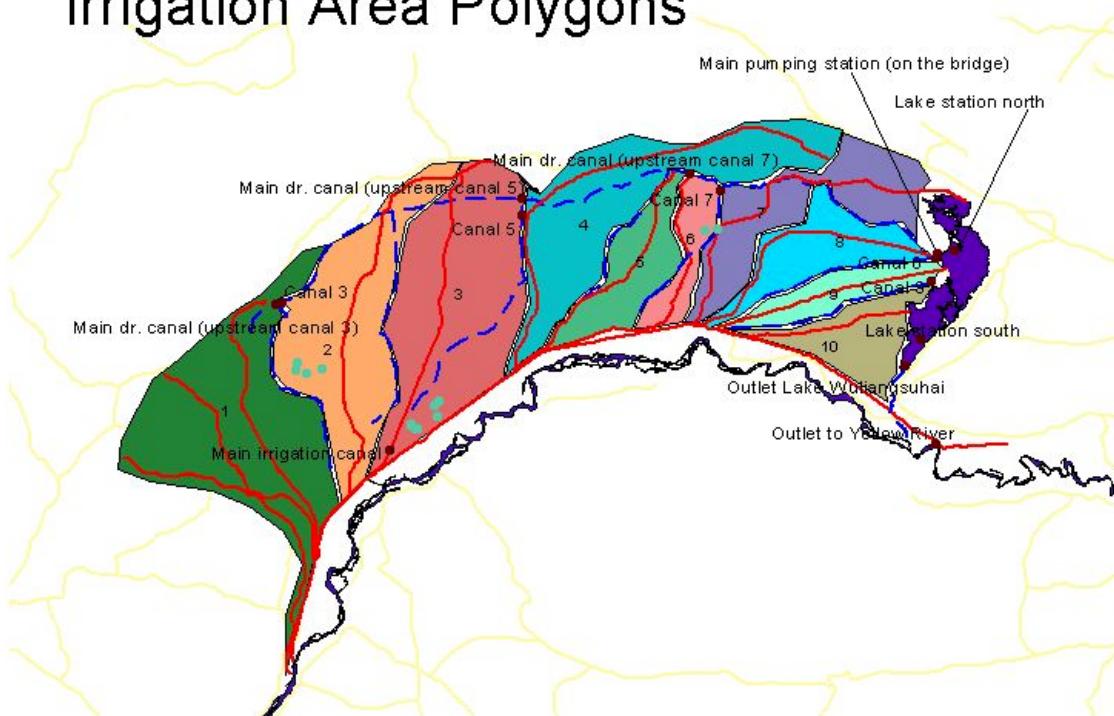

Figure 4.14. A simple hydrological model for the Hetao Irrigation Area.

The input from canals and precipitation as well as the outlet to Yellow River are all measured on a yearly basis. Evapotranspiration can be estimated as the difference of water volumes from Yellow River (used for irrigation) and the water volume introduced to Lake Wuliangsuhai. Input from mountains has not been estimated, however only the northern mountain ridge will possibly affect the irrigation area. In the east the runoff will reach the lake directly and in the south and west there are no contributing mountains.

The conducted water balance for Hetao Irrigation Area and Lake Wuliangsuhai assumes that intake from Yellow River is the dominating source and that evapotranspiration and outlet to Lake Wuliangsuhai are the sinks (outlet to Yellow River is routed through the lake).

The irrigation and drainage water is distributed over a number of areas connected to the different canals, as illustrated below.

Irrigation Area Polygons

Drainage Area Polygons

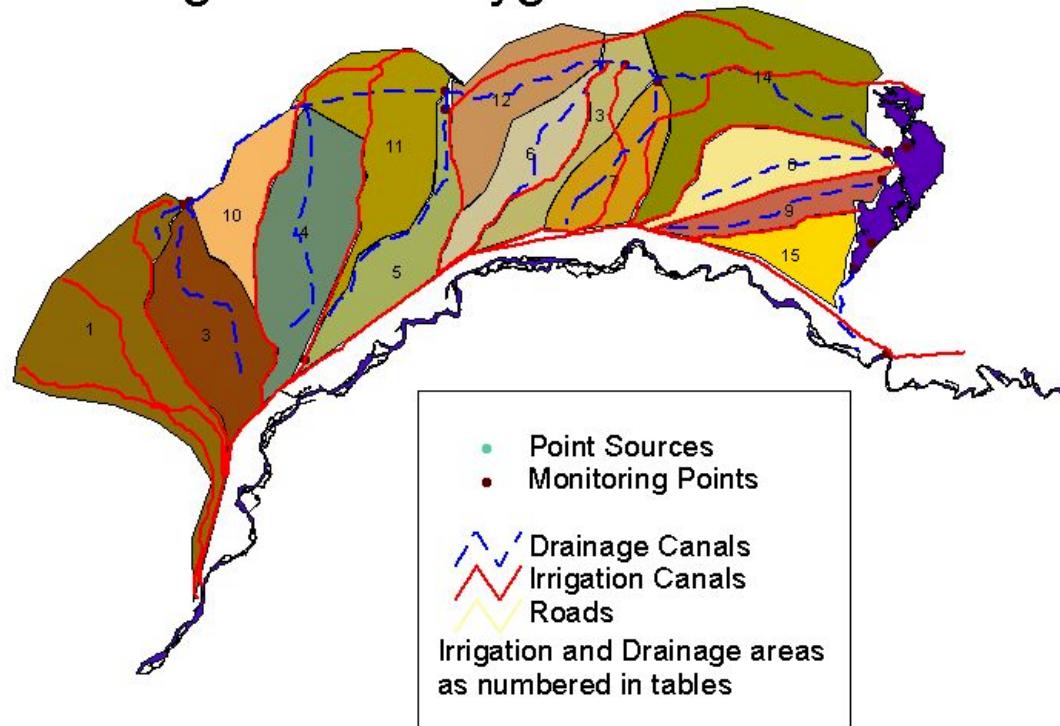

Figure 4.15. Irrigation and drainage area polygons used for calculating the Hetao water budget.

3.5.5 Water Balance for Lake Wuliangsuhai

The simplest hydrological model for Lake Wuliangsuhai is one with 3 inputs (from drainage, from mountains and precipitation) and 2 losses (outlet to Yellow River and evapotranspiration):

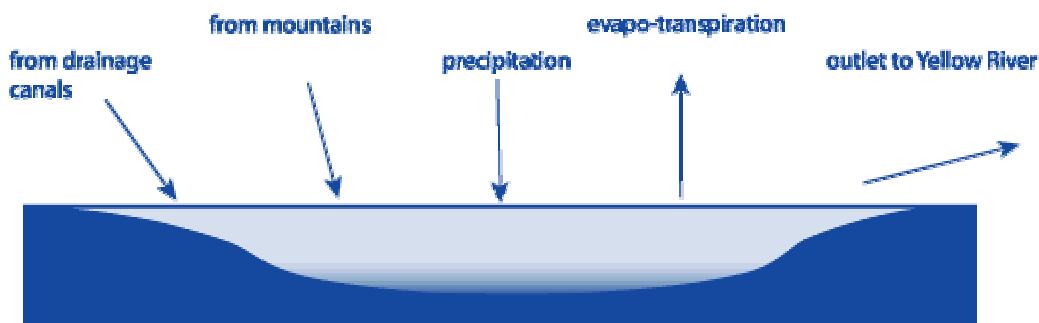

Figure 4.16. A simple hydrological budget for Lake Wuliangsuhai

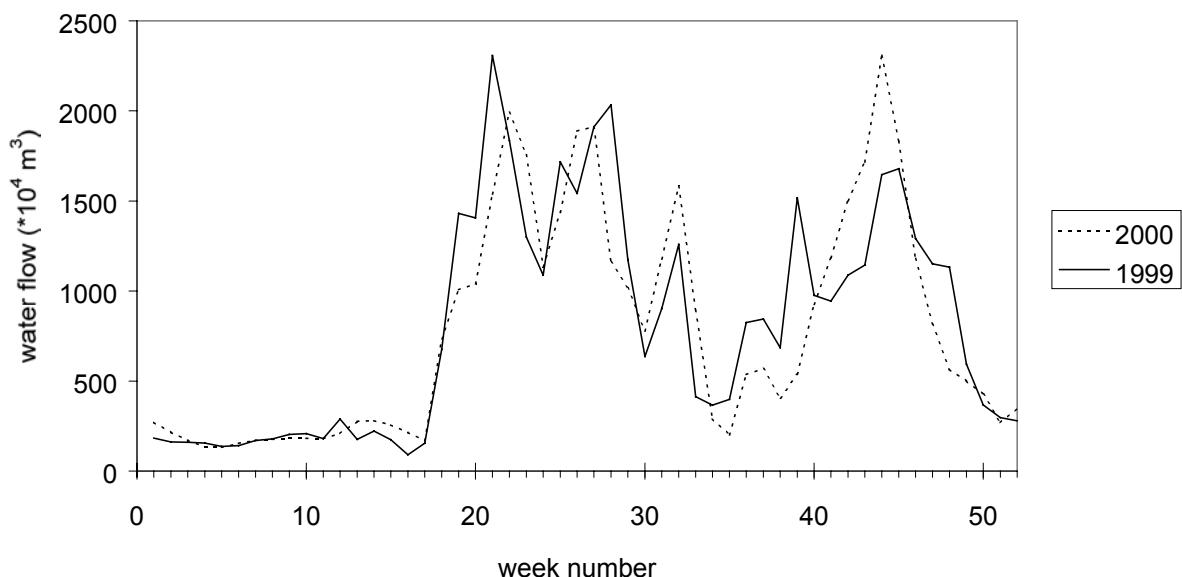

Figure 4.17. Illustration of water input to Lake Wuliangsuhai from canals during 1999 and 2000

| 2001 | 363 | 47 | 31 | 441 | 37 | 404 |

The loss of water by evapotranspiration in Lake Wuliangsuhai is expected to be quite constant from year-to-year since it mainly depends on the following reasonably constant factors: total lake area, reed area and climate. Calculations of difference between total inputs from Hetao and output from the lake are presented in the figure below. Although the inputs vary considerably between years, the loss from the lake is seemingly constant at ca. $400 \times 10^6 m^3/yr$. This implies that the minimum annual water input from canals cannot go below this value without gradually reducing the water level on an annual basis. In addition, timing of the water inputs must be considered together with regulation regime of the outlet dam, not to reduce the water level below accepted levels.

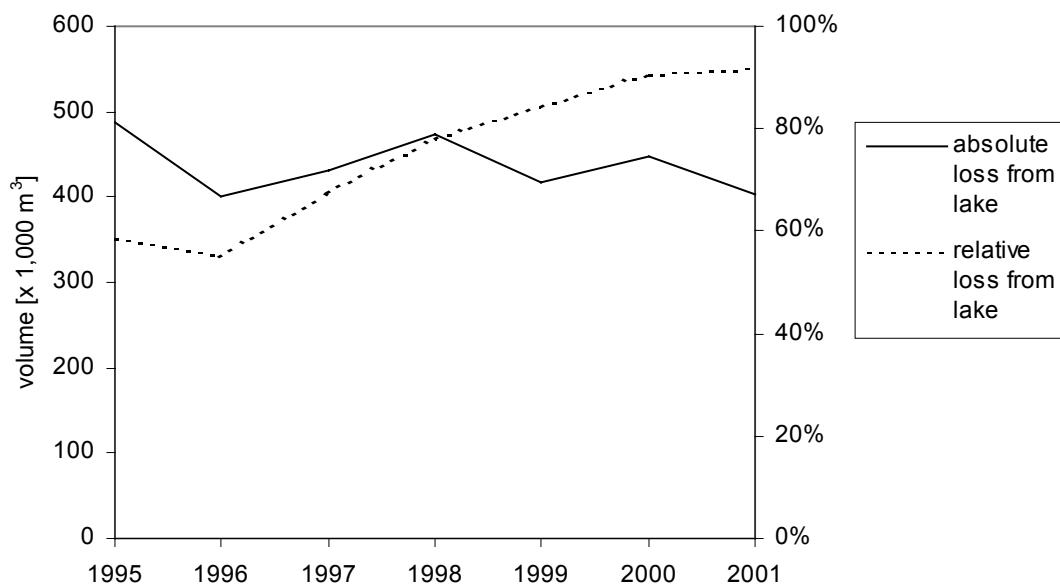

Figure 4.18. Calculated loss of water (m^3/year and % of input) of Lake Wuliangsuhai

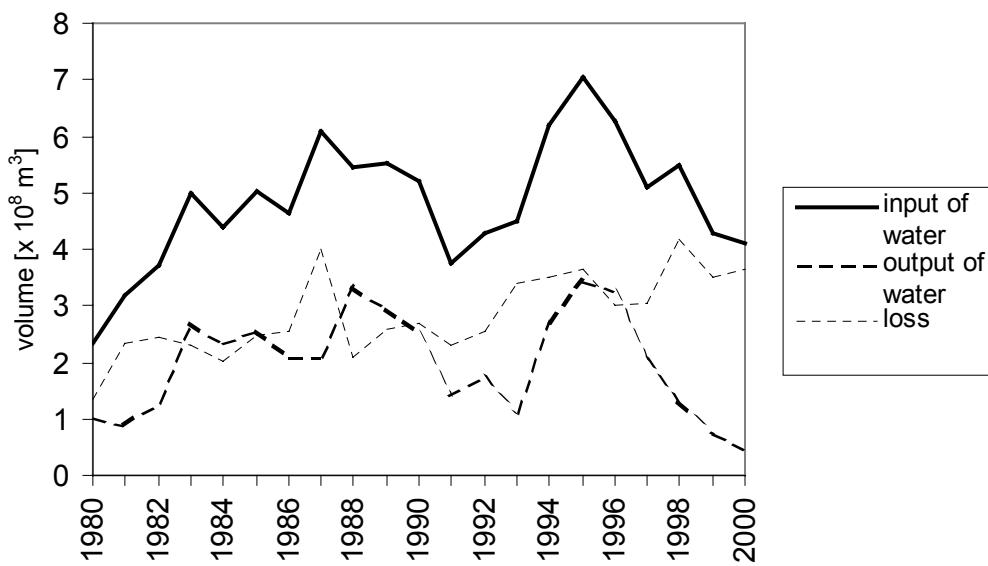

Figure 4.19. Measured input of water to, and output from Lake Wuliangsuhai 1980 - 1995.
Calculated water loss presented by dotted line. Input from mountains are not included.

3.6 Water Quality In Canals

To compare the water quality between canals and years an average for the irrigation season was calculated. This is motivated by the low water flow outside the irrigation period (December to March), which will cause high concentrations of pollutants from industrial wastewater and domestic sewage. These values would otherwise affect the average annual values to a large degree and disturb the comparisons. In addition an average value for the non-irrigation period has been calculated. For practical reasons an irrigation period of 1 May - 1 December was chosen. From this period 2-7 samples were averaged for the years 2001 and 2002.

3.6.1 Mineral salts (Salinity and Main Inorganic Ions)

Despite analyses of water from the Yellow River water (Yongjiqu MIC) from 2001 only, it seems clear that evaporation causes considerable increase in salt content downstream the Hetao system. The highest salt concentrations were observed in canals nos. 7, 8 and 9 as well as in the inlet into Yellow River. In 2001 there was more than a doubling (ca. 125 % increase) of the conductivity and hence the salt content from the Main Irrigation Canal to the Main Pumping Station. A marked increase was also observed between the Main Pumping Station and the outlet of Lake Wuliangsuhan. Here the increase in conductivity was about 85 %. An additional increase in salt content was observed between the lake and the inlet into Yellow River, probably due to inputs from the industries in the Wulateqianqi area. The main cations in the canal and lake water were Sodium (Na), Calcium (Ca) and Magnesium (Mg), while Chloride (Cl) Sulphate (SO₄) and Hydrogencarbonate (HCO₃) were the dominant anions.

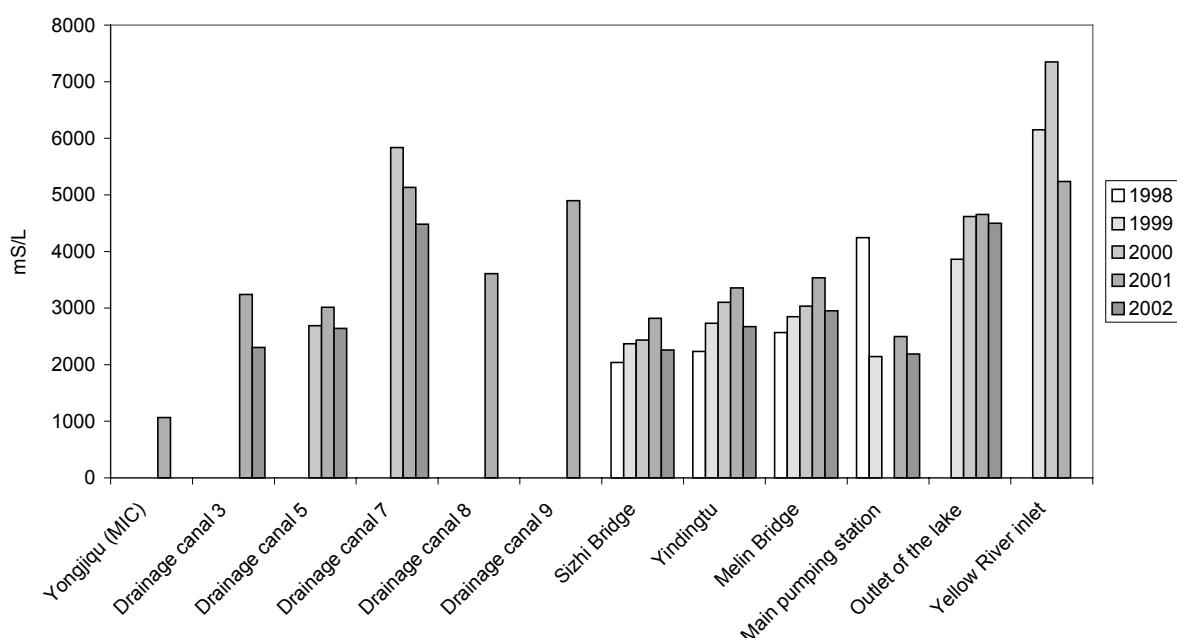

Figure 4.20 Conductivity (mS/m) in canals (averages for irrigation season).

pH

The annual average pH values in the Hetao canal system varied between 7.5 and 8.5, while the outlet of Lake Wuliangsuhai had a pH of around 9. This high value is caused by the high plant production in the lake.

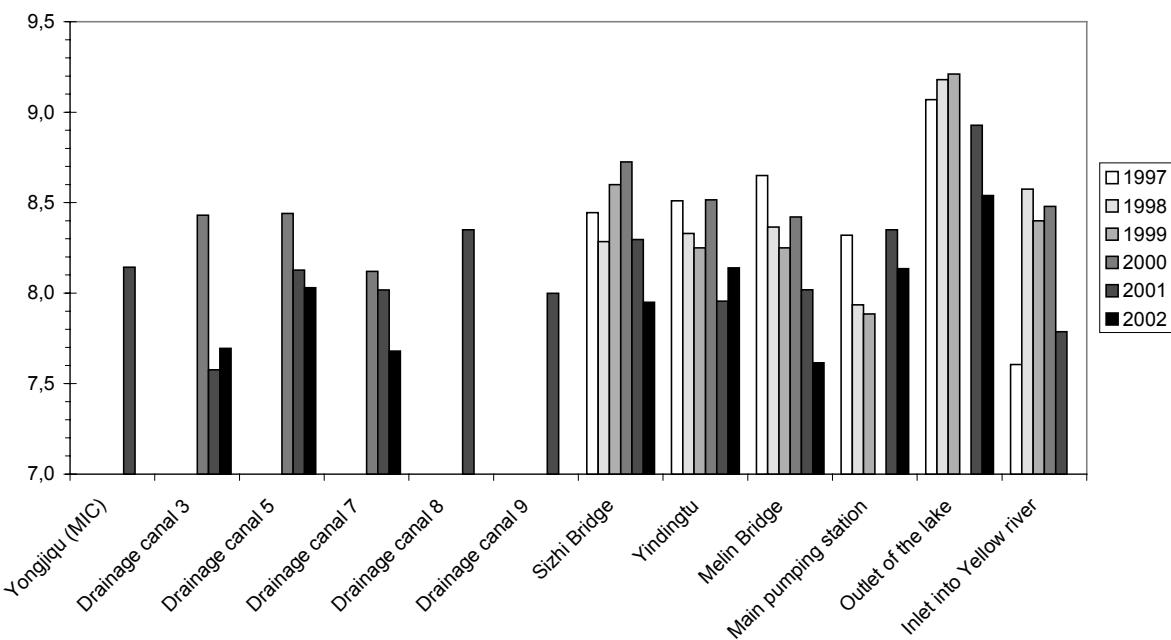

Figure 4.21 pH in canals (averages for irrigation season).

3.6.2 Organic matter (COD, BOD)

Chemical Oxygen Demand (COD)

COD is a standard measure for the amount of oxidizable matter, both biological and non-biological, in water. The COD test predicts the oxygen requirements for effluents and is used for the monitoring and control of water quality.

The annual concentrations of COD were by far the largest in drainage canal no. 7 and in the inlet into Yellow River at Wulateqianqi. This is due to large amounts of industrial wastewater.

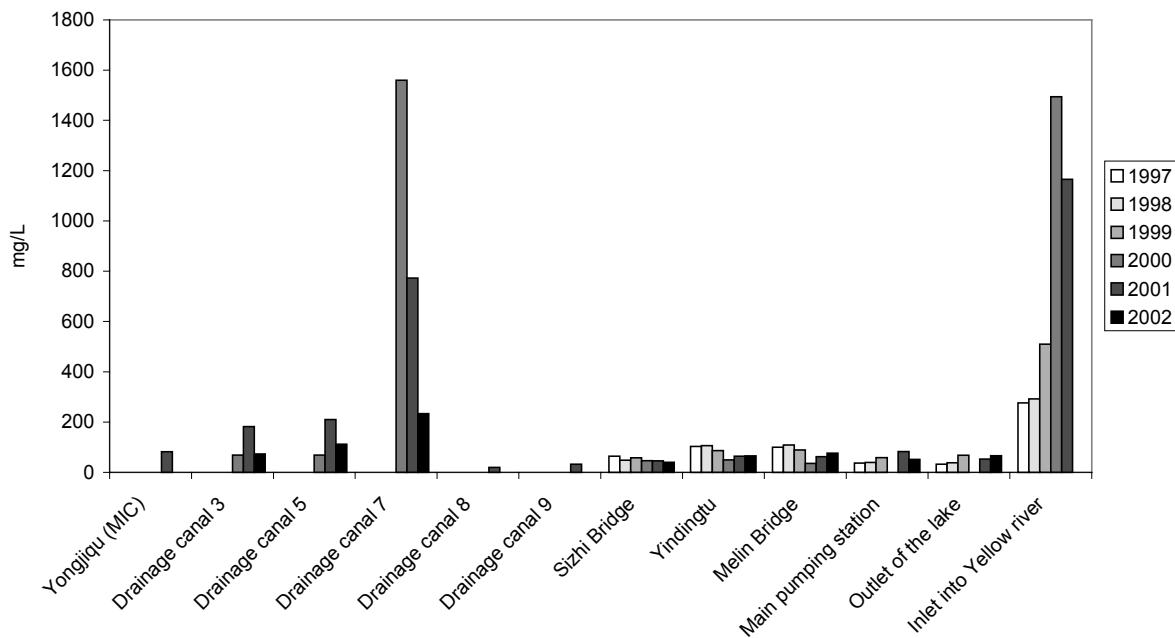

Figure 4.22 Chemical Oxygen Demand (COD) in canals (averages for irrigation season).

Biological Oxygen Demand (BOD_5)

Biochemical Oxygen Demand refers to the amount of oxygen that would be consumed by micro-organisms if all the organic substances in the water were degraded.

The highest values of BOD_5 were observed in Drainage Canal no. 7, but greatly elevated values were also measured in Drainage Canals Nos. 3 and 5 and the inlet into Yellow River.

The relatively low values measured in all stations in the Main Drainage Canal indicate a considerable breakdown and dilution of the organic waste from industries.

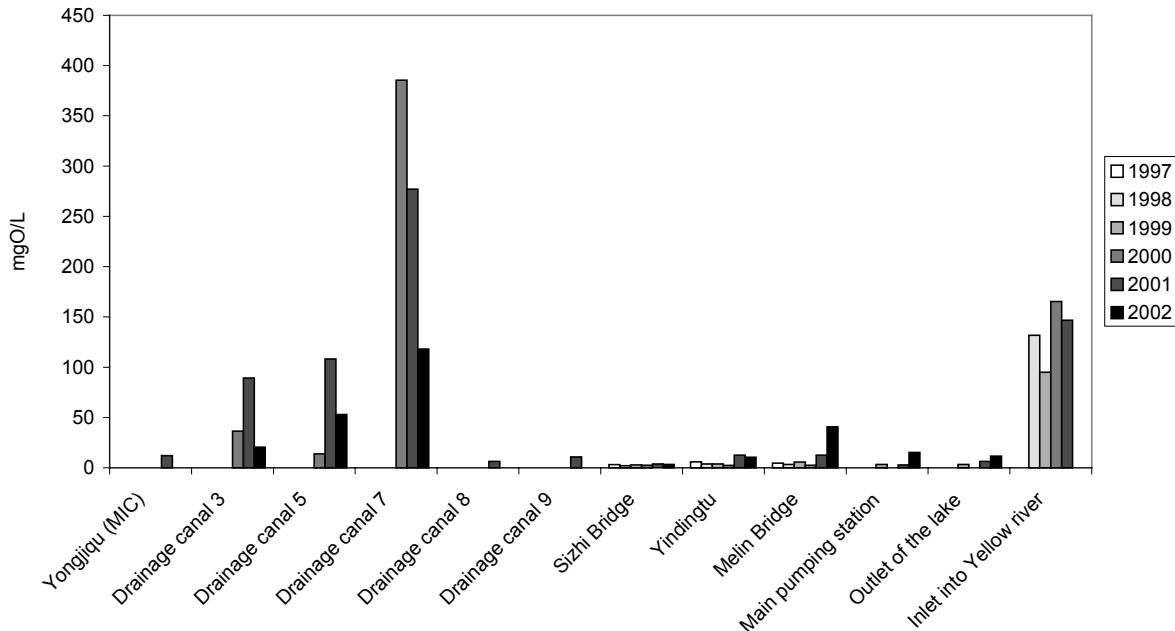

Figure 4.23 Biological Oxygen demand (BOD_5) (averages for irrigation season).

3.6.3 Nutrients (P and N)

Phosphorus (P) and Nitrogen (N) are called major plant nutrients because addition of soluble forms of these minerals will stimulate the growth of plants. Loading of water with these elements may stimulate plants in the water similar to the effect of fertilising farmland. Eutrophication is often an unwanted effect of surplus fertilisation of lakes and rivers.

It is likely that the values of Tot P and Tot N from the Main Irrigation Canal are generally too high due to interference with particles in the Yellow River water, which is very turbid (cf. Methods chapter).

Total P

Very high concentrations of phosphorus were measured in drainage canals nos. 5 and 7 in the years 2001 and 1999 respectively. Still, the concentration was high when the water was pumped into the lake at the Main Pumping Station (average irrigation season values: 0.116 - 0.409 mg P/L). As expected the phosphorus concentrations in the water were about halved before leaving the lake due to biological uptake and sedimentation. Consequently, the lake is a net trap for phosphorus. However, the phosphorus concentrations were markedly increased before the outlet canal enters The Yellow River, probably because of large amounts of effluents from the Wulateqianqi area.

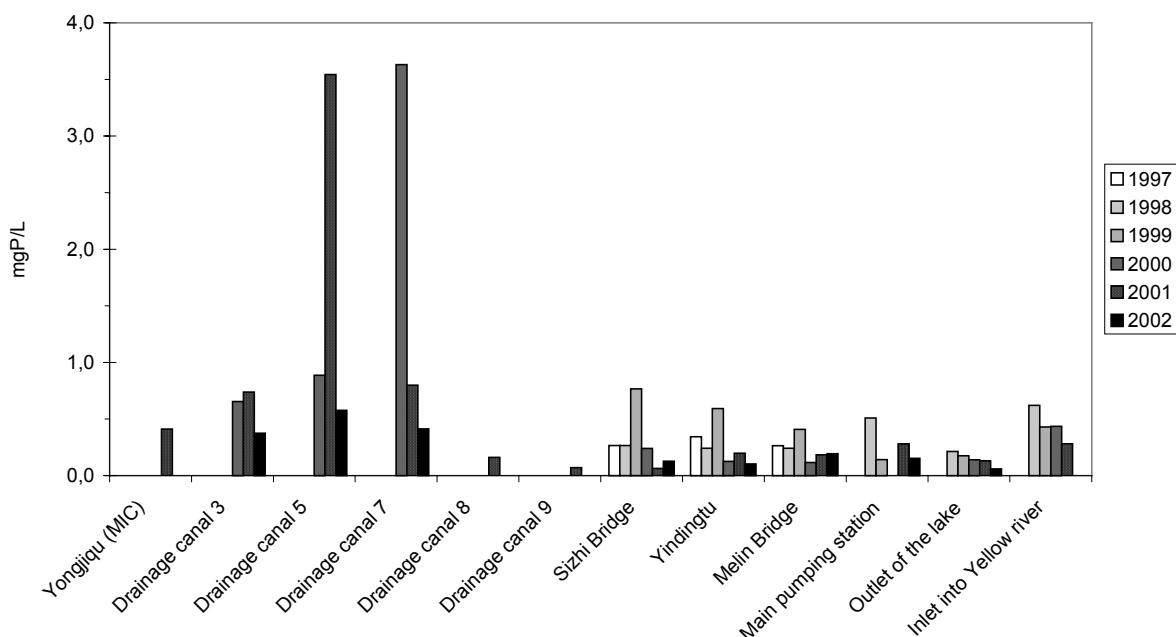

Figure 4.24 Total Phosphorus in canals (averages for irrigation season).

The highest concentrations of nitrogen were measured in the Drainage Canals nos. 3, 5 and 7. The concentrations in the Main Drainage Canal, where monitoring data exist for a number of years, the average values were higher in 2001 and 2002 than in the years before. The same effect is observed in the inlet into Yellow River.

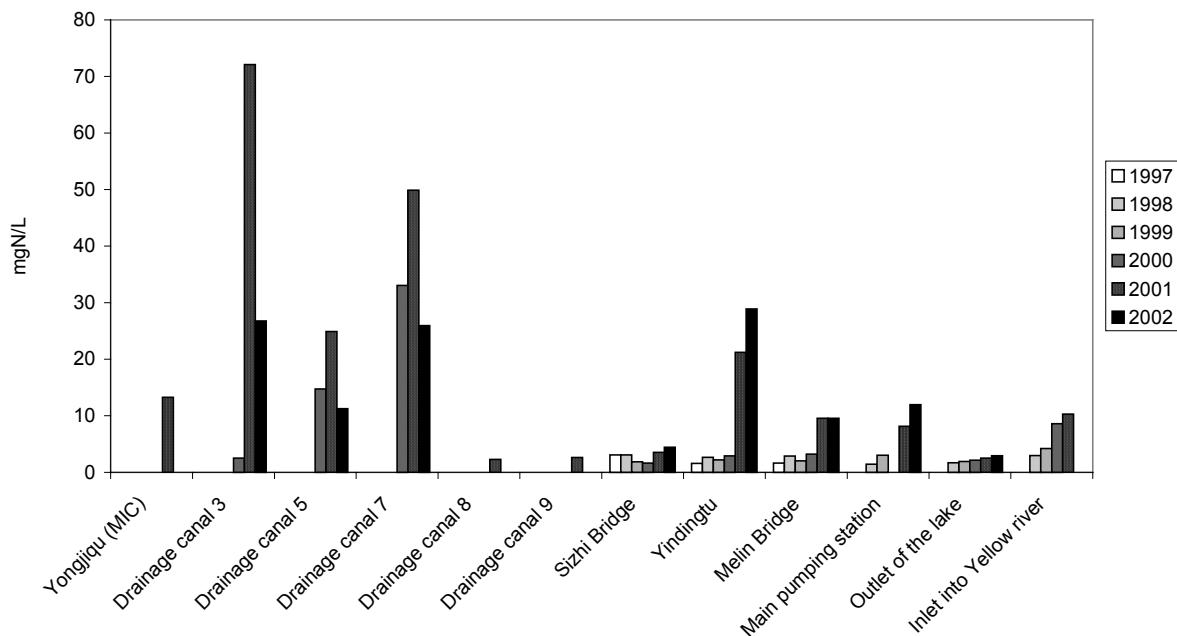

Figure 4.25 Total Nitrogen in canals (averages for irrigation season).

3.6.4 Metals

Metals are elements naturally occurring in rock and soils, but they are normally firmly bound to minerals. Certain metals are harmful to man and nature even at very low concentrations, especially mercury, lead, cadmium, zinc and chromium. These metals can be found in high concentrations in some industrial and urban wastewaters.

Cadmium (Cd)

The average concentrations of cadmium were not especially high compared to Chinese Water Quality Standards, e.g. Class I-II. Highest mean values (Class II) were recorded at the Inlet to Yellow river in 2001 and in canal stations Melin Bridge and Yindingtu in 1999.

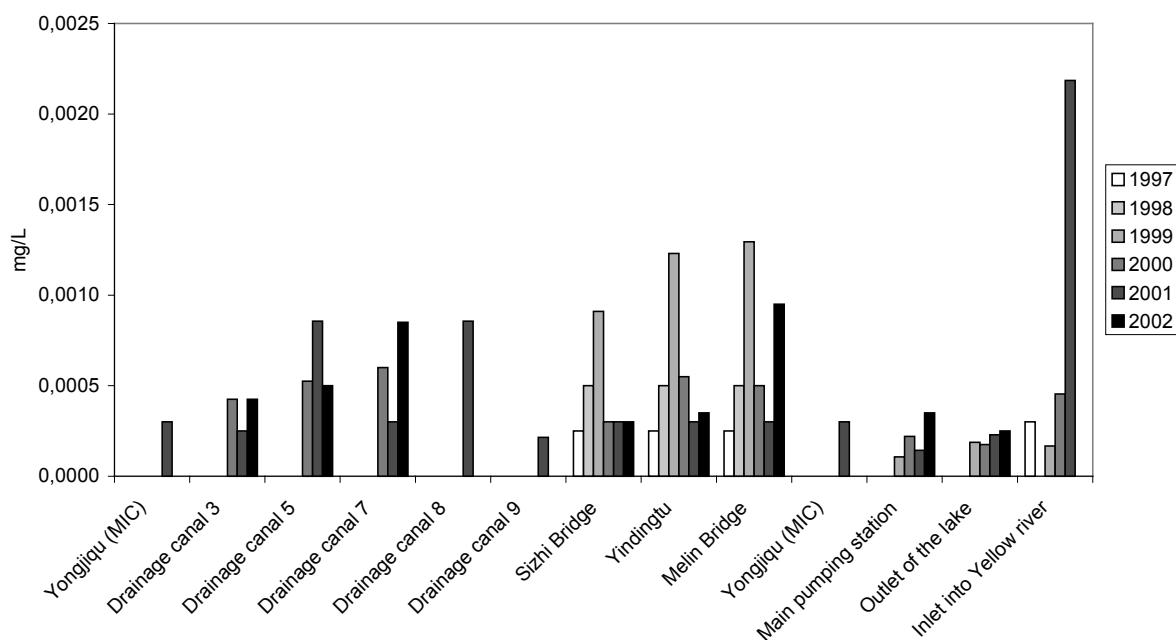

Figure 4.26 Cadmium in canals (averages for irrigation season).

Cromium (Cr6+)

The mean values of chromium were high (Class V) at the Main Pumping Station in 2000 and very high at the Inlet to Yellow River in 1999 and 2000 (exceeding Class V). The mean concentrations in other canal stations and at the Outlet of the lake were markedly lower (Class I-IV).

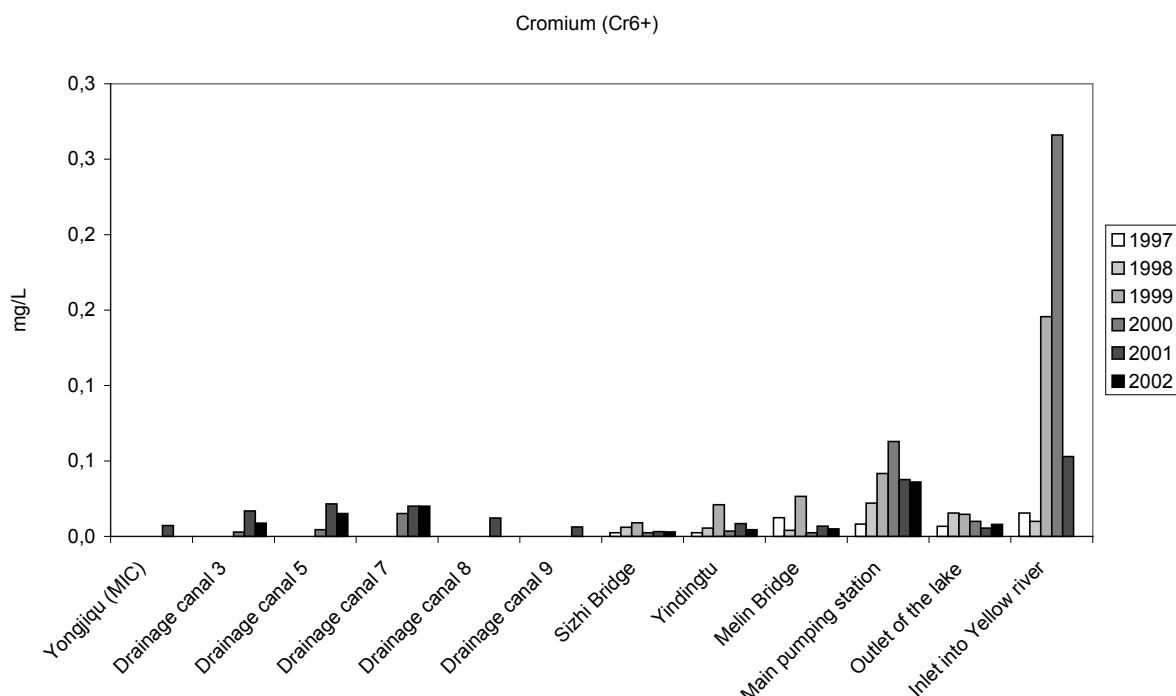

Figure 4.27 Chromium in canals (averages for irrigation season)

3.6.5 Arsenic and Cyanide

Arsenic is an element widely distributed in the earth's crust. In some areas, among them Hetao, high concentrations of arsenic can be found in groundwater. The chemical properties of cyanide make it a widespread ingredient in many industrial processes. Both these toxic substances dissolve in water and therefore national and international standards require very low concentrations in drinking water.

Arsenic (As)

The yearly mean values of arsenic were mostly relatively low according to Chinese Water Quality Standards (Class I-III) in drainage canals and in the Outlet of the Lake. However, a marked increase was observed from the Outlet of the lake to the Inlet into Yellow river. Here the mean value exceeded Class V in 1999, but decreased in 2000 and 2001.

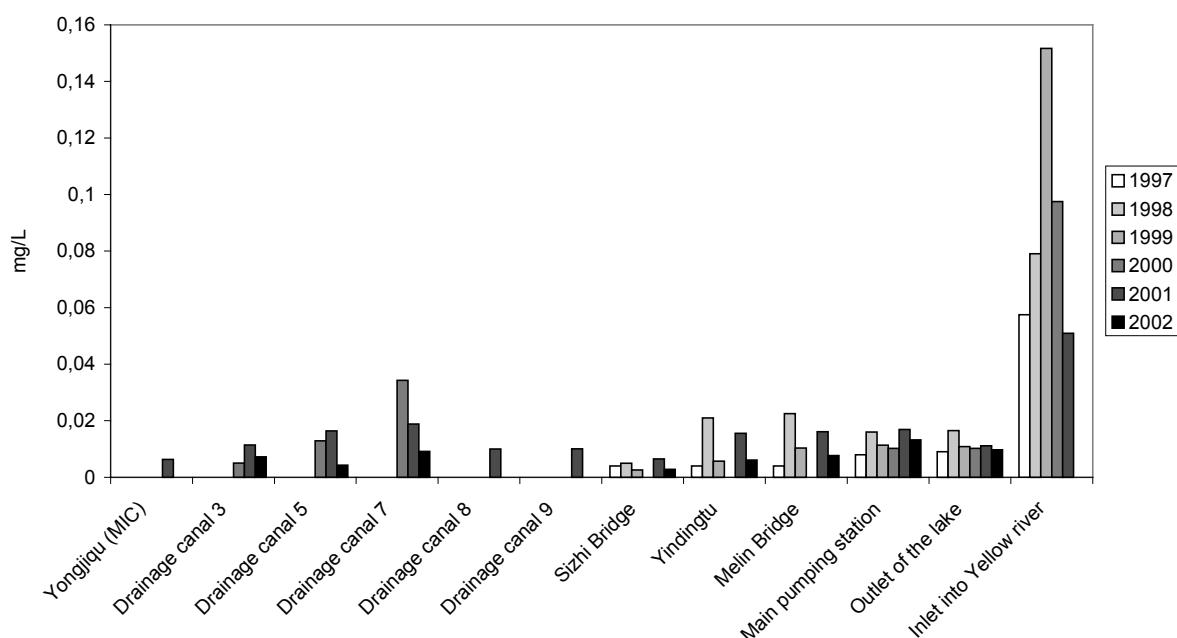

Figure 4.28 Arsenic in canals (averages for irrigation season)

Cyanide (CN)

The concentrations (mean values) of cyanide were mostly low according to Chinese Water Quality Standards (Class I-II).

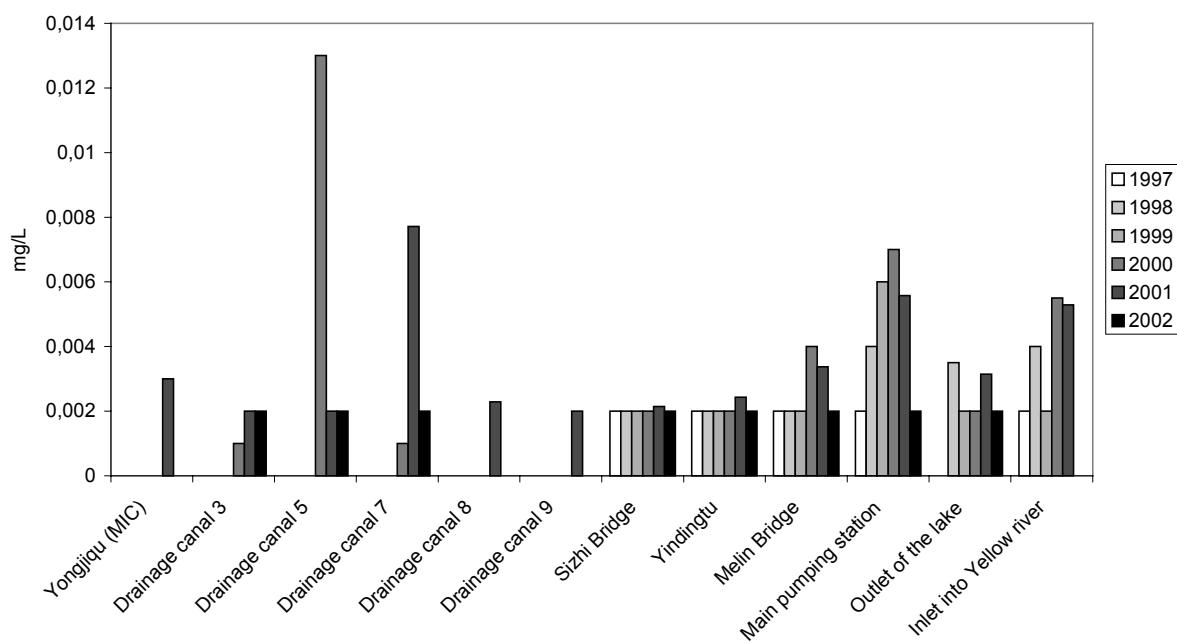

Figure 4.29 Cyanide in canals (averages for irrigation season)

Water classification (selected variables)

A water classification index was calculated by dividing the average concentration with the class limits for each class. In this way the exceedance rate of each limit is given in Appendix.

Table 4.7 Water classification concentrations limits for classes no. 3, 4 and 5.

| BOD5 mg/L | COD mg/L | CODmn mg/L | NH4-N mg/L | NO2-N mg/L | NO3-N mg/L | PO4-P mg/L | total N mg/L | total P mg/L |
|----------------------------------|-------------|---------------|---------------|---------------|---------------|---------------|-----------------|-----------------|
| Chinese Standard (Canals) | | | | | | | | |
| class 3 | 4 | 20 | 6 | 1 | | 10 | 1 | 0,2 |
| class 4 | 6 | 30 | 10 | 1,5 | | | 1,5 | 0,3 |
| class 5 | 10 | 40 | 15 | 2 | | | 2 | 0,4 |
| Exceed class 5 | | | | | | | | |

Average concentrations for non-irrigation and irrigation periods were calculated, respectively, and water quality classes presented in the tables below. For most important parameters the water quality was beyond class 5 in most drainage canals during the non-irrigation period. The situation was only slightly better during the irrigation period.

Table 4.8 Average values and water quality classes for canal stations in the non- irrigation period

Average values for the two periods given with numbers

| Non-Irrigation Period, Canals | BOD5 mg/L | COD mg/L | CODmn mg/L | NH4-N mg/L | NO2-N mg/L | NO3-N mg/L | PO4-P mg/L | total N mg/L | total P mg/L |

3.7 Transport Of Substances In Canals

Transport of measured substances is calculated for the Main Pumping Station and for the outlet of the lake for the irrigation period, and presented in the table below.

Table 4.10 Calculated transport of suspended solids, organic matter and nutrients during irrigation periods.

| | | COD tons | BOD5 tons | Tot P tons | Tot-N tons |
|-------------|------|-------------|--------------|---------------|---------------|
| Main P. St. | 1997 | 18230 | | | |
| | 1998 | 21536 | | 189 | 689 |
| | 1999 | 21948 | 1 239 | 71 | 1 084 |
| | 2000 | 25768 | 1 008 | 28 | 722 |
| | 2001 | 10398 | 3 485 | 181 | 2 273 |
| | 2002 | 14620 | 3 718 | 60 | 3 595 |
| Average | | 18750 | 2 363 | 106 | 1 673 |
| Lake outlet | 1997 | 4107 | | | |
| | 1998 | 272 | | 1,8 | 13 |
| | 1999 | 4809 | 13 | 9,3 | 87 |
| | 2000 | 203 | 5 | 0,2 | 5 |
| | 2001 | 12902 | 1 790 | 38,1 | 586 |
| | 2002 | 284 | 27 | 0,4 | 5 |
| Average | | 3763 | 459 | 10 | 139 |

The Main Pumping Station stands for the major part (probably approximately 90%) of the inputs of nutrients and organic matter to Lake Wuliangsuhai. The variations between different years are quite large both for nutrients and organic matter. Although there are large uncertainties in the calculations of the mass transportation, it gives a rough estimate of the input to the lake. It also indicates that a considerable amount of nutrients and organic matter is held back in the lake during the irrigation season.

3.8 Water Quality In The Lake

3.8.1 Lake water level

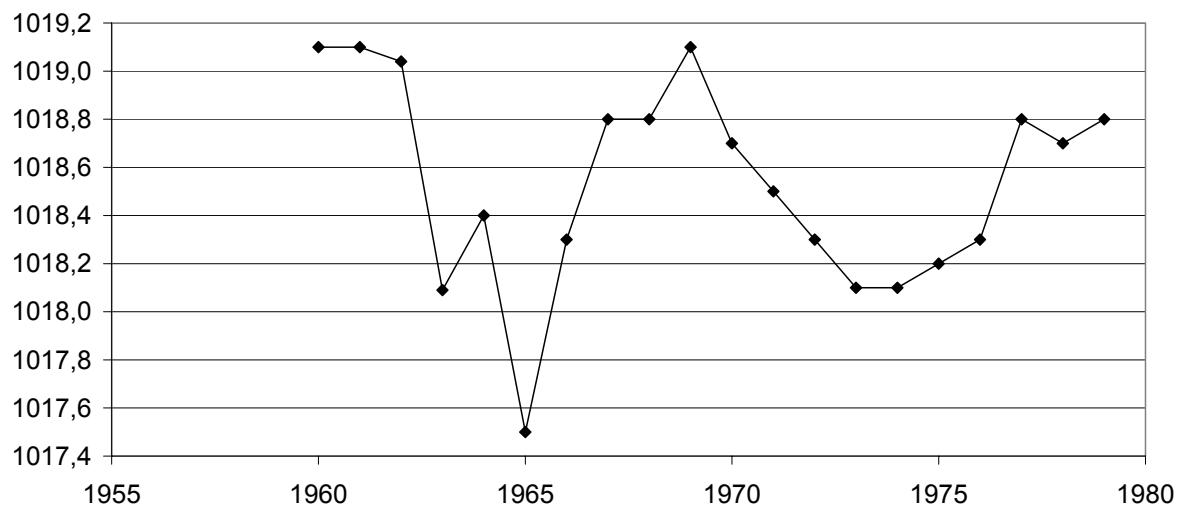

Figure 4.30 Annual average water level in Wuliangsuhai 1960-1979

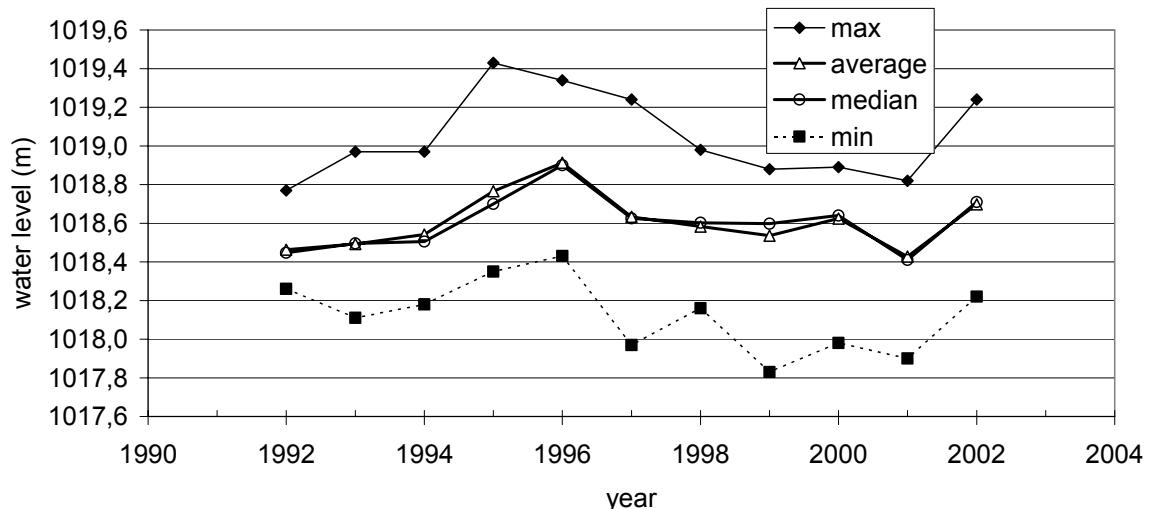

Figure 4.31 Annual average, median, maximum and minimum water level in Lake Wuliangsuhai 1992-2002

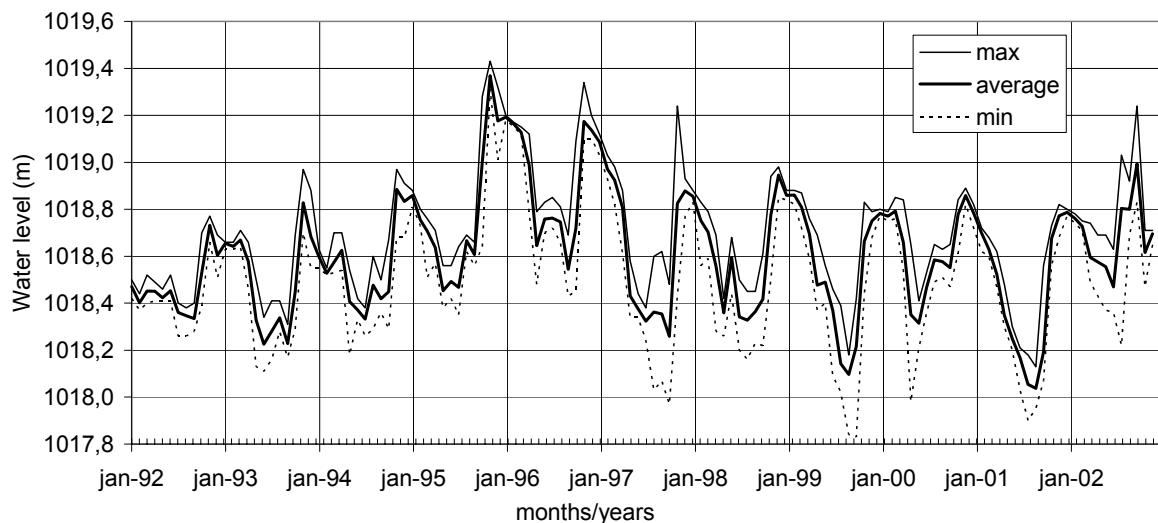

Figure 4.32 Average monthly water level 1992-2002

3.8.2 Salinity

Salinity is a measure of the total concentration of mineral salts dissolved in the water (g/kg), and is given in the unit ‘parts per thousand’ or ‘o/oo’. In temperate, humid regions freshwater lakes normally have ‘soft water’ with low salinity, whereas high salinity is a typical feature of lake water in arid regions. In the southern basin of Lake Wuliangsuhai the salinity in 2001 was 2,4 o/oo. Characteristic salinity for oceanic waters is ca. 35 o/oo.

Below we calculated the salinity of Lake Wuliangsuhai at both stations where water quality was measured in 1987/88 and 2001. The salinity almost doubled during this period.

Table 4.11. Salinity in Lake Wuliangsuhai in 1987/88 and 2001.

| Lake Station | | Lake Station | | |
|-------------------|------------|--------------|------------|------------|
| North | | South | | |
| 1987-88 | 2001 | 1987-88 | 2001 | |
| mg/l | mg/l | mg/l | mg/l | |
| Na | 219,7 | 353,3 | 339 | 664,9 |
| K | 5,9 | 22,2 | 6,1 | 33,8 |
| Ca | 39,7 | 117,1 | 33,4 | 43,3 |
| Mg | 44,4 | 75,8 | 79,4 | 165,7 |
| Cl | 243,1 | 524,3 | 431,6 | 997,5 |
| SO ₄ | 236,4 | 320,3 | 316,8 | 538,7 |
| HCO ₃ | 12,6 | 12,76 | 7,5 | 13,5 |
| CO ₃ | 0,9 | 1,19 | 4,6 | 3,2 |
| Sum mg/L | 802,7 | 1427,0 | 1218,4 | 2460,6 |
| Sum g/L | 0,80 | 1,43 | 1,22 | 2,46 |
| Salinity = | | | | |
| g/kg | 0,8 | 1,4 | 1,2 | 2,4 |

3.8.3 pH

There seems to be a tendency towards higher pH values in 2000 and 2001 compared to the previous years. This indicates a higher plant production in recent years, but the result may be affected by the higher number of measurements in 2000 (10) and 2001 (4) than in 1997-1999 (3).

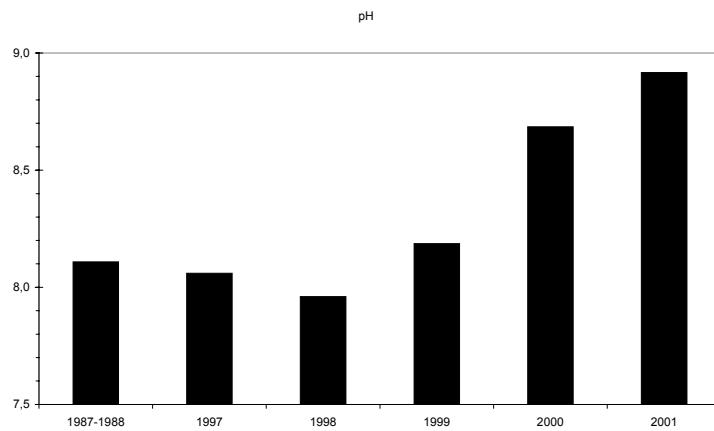

Figure 4.33 Average summer pH in Lake Wuliangsuhai 1967-2001

3.8.4 Nutrients

Total P

Average for ice-free seasons

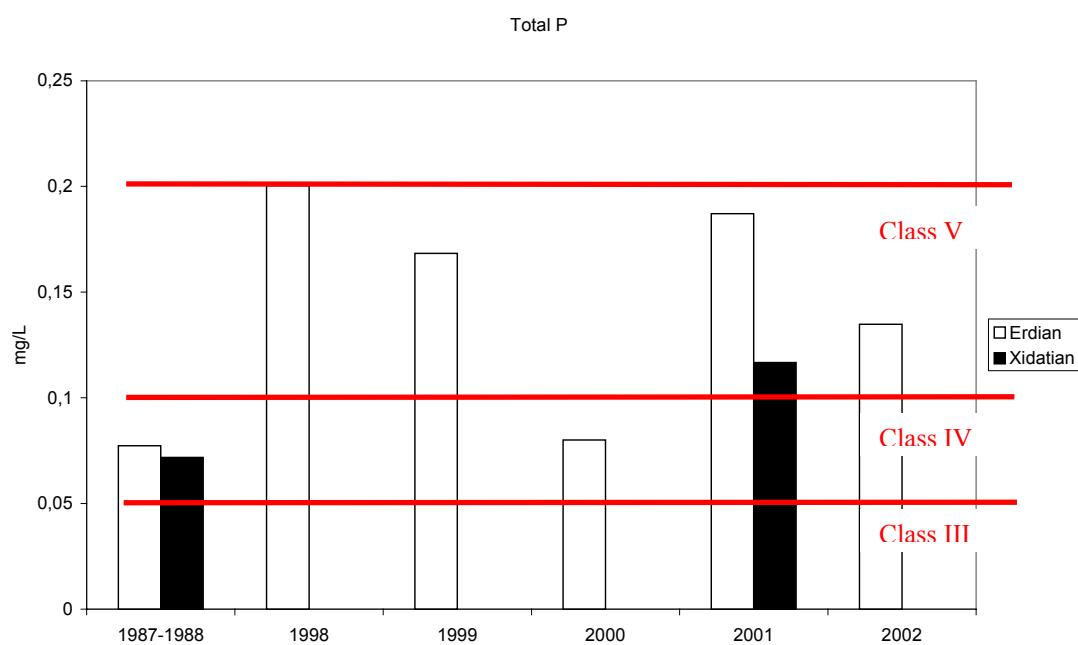

Figure 4.34 Summer average concentrations of total-P in Lake Wuliangsuhai. Upper limit values for Chinese Water Quality classes III; IV and V are given.

In 2001 the number of samples taken in the lake was high enough to allow a comparison of the temporal change of phosphorous at the two sampling stations in the lake throughout the year. In February, under the ice, the concentrations were high (0,4-0,5 mg P/L) at both stations. This is probably due to release of phosphorus from the sediment during low oxygen conditions, in combination with high concentration in inputs from the Main Pumping Station.

After ice-break the concentration was reduced at both stations. However, in Erdiar (the deepest central area of the lake) the concentration increased to winter levels in June, while the concentration only slowly increased at Xidatian (close to Main Pumping Station) from April to August to reach a maximum value of below 0,250 mg P/L in July.

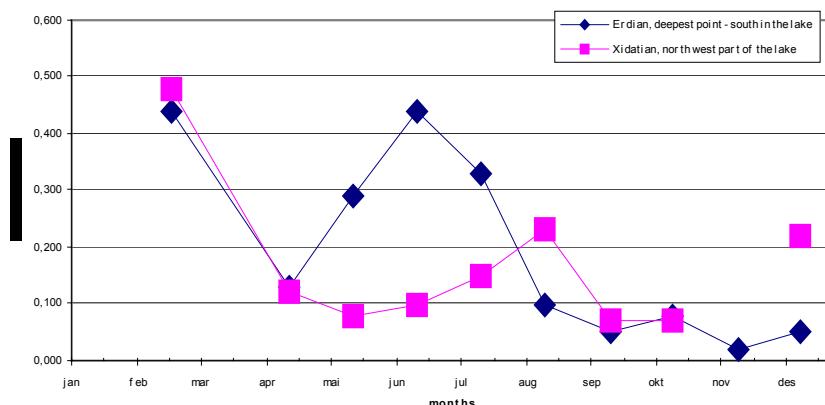

Figure 4.35 Total-P at two stations in Lake Wuliangsuhai during 2001

Total N

Average for ice-free seasons

High values in 2001 compares with higher values in the input from Main Pumping Station in 2000 and 2001.

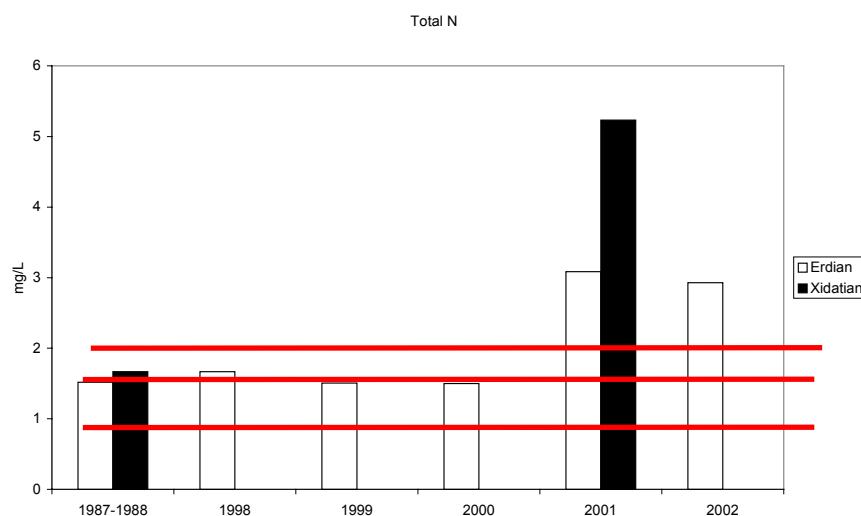

Figure 4.36 Average summer concentrations of Total-N in Lake Wuliangsuhai. Upper limits for water quality classes III, IV and V are indicated.

Water quality classification in the lake

Table 4.12 The Chinese water quality standard class for surface water (GB 3838-2002) for the most relevant variables in lakes with upper concentration limits for the different variables.

| | BOD5 mg/L | COD mg/L | CODmn mg/L | NH4-N mg/L | NO2-N mg/L | NO3-N mg/L | PO4-P mg/L | total N mg/L | total P mg/L |
|--------------------------------|--------------|-------------|---------------|---------------|---------------|---------------|---------------|-----------------|-----------------|
| Chinese Standard (Lake) | | | | | | | | | |
| class 3 | 4 | 20 | 6 | 1 | | 10 | | 1 | 0,05 |
| class 4 | 6 | 30 | 10 | 1,5 | | | | 1,5 | 0,1 |
| class 5 | 10 | 40 | 15 | 2 | | | | 2 | 0,2 |
| Exceed class 5 | | | | | | | | | |

The discharge of organic matter into the lake from the Hetao area is so large that the water quality for these variables are beyond the classification standard (exceed class V), when measured as BOD₅ and COD. Only in the Erdiar during summer the organic content is within the limits off class V. For nitrogen the water quality class is beyond class V at both lake stations, except at Erdiar during winter. A large part of the Total nitrogen was present at ammonium. Total P was in class V the whole year around in the southern basin, while the Xidatian was beyond class V in winter.

The water quality was generally better in the southern part of the lake (Erdiar) than in the northern basin close to the Main Pumping Station (Xidatian), for Nitrogen (Total N, NH₄, NO₂ and NO₃), but not for Total P and organic substances (BOD₅ and COD). However, during the non-irrigation period the Total P concentration was also markedly higher at Xidatian than at Erdiar. These evaluations are based on average values for all sampling years (1987-2002).

The water quality tends to be better in the irrigation period compared to the non-irrigation period at both lake stations. The table below show both the average concentrations (with numbers) and the water quality class (colour according to standard classes to the left on the preceding table).

*Table 4.13 Comparison of water quality classes in irrigation and non-irrigation periods.
Numbers in this table refer to the average seasonal concentration while the colour is the water quality standard class for surface water.*

| Non-Irrigation Period, Lake | BOD5 mg/L | COD mg/L | CODmn mg/L | NH4-N mg/L | NO2-N mg/L | NO3-N mg/L | PO4-P mg/L | total N mg/L | total P mg/L |
|--------------------------------|--------------|-------------|---------------|---------------|---------------|---------------|---------------|-----------------|-----------------|
| Lake station, North | 12,83 | 91,63 | 11,56 | 9,47 | 0,03 | 0,43 | | 25,15 | 0,51 |
| Lake station South | 16,23 | 127,23 | 7,49 | 0,41 | 0,01 | 0,11 | | 1,89 | 0,15 |
| Irrigation Period, Lake | | | | | | | | | |
| Lake station, North | 10,86 | 50,48 | 7,55 | 2,00 | 0,18 | 0,28 | | 6,91 | 0,13 |
| Lake station South | 6,69 | 67,90 | 10,24 | 0,32 | 0,04 | 0,13 | | 3,13 | 0,17 |

3.8.5 Transparency

Unfortunately, systematic measurements on Secchi disk transparency were not carried out. However, some occasional observations showed that the transparency was less than to the

bottom both at Xidatian and Erdiar. Generally the transparency seemed to be lower at Xidatian than at Erdiar.

3.8.6 Metals and cyanide

Table 4.14 Average values for ice-free season of metals and cyanide (mg/L) for two stations in Lake Wuliangsuhai

| Station | year | Hg mg/L | Pb mg/L | Cd mg/L | Cr6+ mg/L | Zn mg/L | Cu mg/L | Fe mg/L | As mg/L | Cyanide mg/L |

Table 4.15 Chinese classification class III upper limits for some metals, arsenic and cyanide (mg/L).

| | Hg | Pb | Cd | Cr | Zn | Cu | Fe | As | Cyanide |
|--|--------|------|-------|------|-----|-----|-----|------|---------|
| | 0,0001 | 0,05 | 0,005 | 0,05 | 1,0 | 1,0 | 0,8 | 0,05 | 0,2 |

Most average values for these variables for both lake stations belong to the Class I-III. However mercury was in class IV at Erdiar in 1999, and chromium in class II-IV at Xidatian in 2001 and at Erdiar in 1997-1999. Generally the concentrations were higher at Xidatian than at Erdiar (2001). For chromium the average concentration was approximately 5 times higher at Xidatian than at Erdiar.

3.8.7 Phytoplankton

Genera and biomass

A list of the phytoplankton genera found in Lake Wuliangsuhai is given below.

Table 4.16 Phytoplankton genus list of Lake Wuliangsuhai

| Cyanophyta | Bacillariophyta |
|----------------------------|------------------------------------|
| 1. Dactylococcopsis Hansg. | 31.Cyclotella Eutz. |
| 2.Gloeothece | 32.Cymbella Ag. |
| 3.Lyngbya | 33.Navicula Bory. |
| 4.Chroococcus Nag. | 34.Fragilaria Lyng. (Synedra Ehr.) |
| 5.Gomphosphaeria | 35.Suirella Turp. |
| 6.Microcystis Kutz. | 36.Cocconeis Ehr. |
| 7.Phormidium Kutz. | 37.Amphiprora Ehr. |
| 8.Merismopedia Mey. | 38.Asterionella |
| 9.Spirulina Turp. | 39.Nitzschia closterium |
| 10.Coelosphaerium Nag. | 40.Diatoma De Cand |
| 11.Raphidocelis Hin.. | 41.Chaetoceros Ehr. |
| 12.Nostoc Vauch | 42.Rhopalodia Mull. |
| Chlorophyta | 43.Meridion Ag. |
| 13.Ankistrodesmus Cord | 44.Fragilaria Lyngby |
| 14.Scenedesmus Mey. | Chrysophyta |
| 15.Chlamydonmonas Ehr. | 45.Chrysococcus |
| 16.Kirchneriella Schm. | 46.Chromulina Cienk. |
| 17.Chlorococcum Fries. | 47.Ochromonas Wystozki |
| 18.Crucigenia Morr. | Cryptophyta |
| 19.Closterium Nitzsch. | 48.Cryptomonas Ehr. |
| 20.Actinastrum Lag. | 49.Chroomonas Hansg. |
| 21.Golenkinia Chod. | Dinophyta |
| 22.Oocystis Nag | 50.Gymnodinium Stein |
| 23.Micractinium | Euglenophyta |
| 24.Tetraedron Kuetz. | 51.Euglena Ehr. |
| 25.Pediastrum Mey. | Xanthophyta |
| 26.Dictyosthaerium | 52.Ophiocytium |
| 27.Coleastrum | |
| 28.Chodatella Lemm. | |
| 29.Cosmarium Cord. | |
| 30.Chlorella Beij. | |

The average biomass of each phytoplankton class and the total biomass for the two stations are given in the next table. The total phytoplankton biomass was very high at Xidatian with an average of 27.0 mg/L, which is characteristic for highly eutrophic (hypereutrophic) lakes. The

biomass at Xidatian (total average) was 9 times higher than at Erdiar. Still the biomass at Erdiar can be characterized as quite high corresponding to eutrophic conditions. Considering field observations of relatively low algal biomasses in Lake Wuliangsuhai, the calculated biomasses seem to be too high. One probable reason could be the uncertainties because the identifications were not done to species but only to the genera level.

The phytoplankton biomass at Xidatian was dominated by Bacillariophyta and Euglenophyta. Besides this there were also high biomasses of Chlorophyta, Cryptophyta and Cyanophyta. At Erdiar the phytoplankton was dominated by Bacillariophyta and Cryptophyta with also quite high amounts of Chlorophyta and Cyanophyta. A significant part of the algae in the Lake Wuliangsuhai phytoplankton, especially the Bacillariophyta, probably arises from resuspension from the bottom or from the submerged vegetation.

Table 4.17 Average phytoplankton biomass of Lake Wuliangsuhai in 2001 unit: mg/L

| Community Sampling point | Cyano-phyta | Chloro-phyta | Bacillario-phyta | Chryso-phyta | Crypto-phyta | Dino-phyta | Eugleno-phyta | Xantho-phyta | Total |
|--------------------------|-------------|--------------|------------------|--------------|--------------|------------|---------------|--------------|-------|
| Xidatian | 2.05 | 3.50 | 11.56 | 0.02 | 3.08 | 1.05 | 5.61 | 0.134 | 27.0 |
| Erdiar | 0.30 | 0.38 | 0.65 | 0.01 | 0.589 | 0.19 | 0.088 | | 2.85 |
| Average | 1.18 | 1.94 | 6.10 | 0.01 | 1.83 | 0.62 | 2.85 | 0.067 | 14.6 |

3.8.8 Zooplankton

Species and biomass

According to investigations in 2000-2001, 35 species of zooplankton were found in the Lake Wuliangsuhai, among which 4 species were Protozoa (11% of the total number of species); 22 species of Rotifera (63%); 6 species of Cladocera (17%) and 3 species of Copepoda (9%). In terms of annual average density, the dominant zooplankton were *Ciliata*, *Brachionus angularis* and copepod nauplia.

Among the four groups of zooplankton, Protozoa had the highest density, Rotifera had the highest biodiversity in terms of species numbers, and Copepoda had the highest biomass. The average biomass of Lake Wuliangsuhai was 12.5 mg/L. The highest peak of total zooplankton biomass occurred in April-May. Monthly changes of zooplankton biomass showed a decline with a maximum value of 89.84 mg/L in April 2001. Of the two sampling stations, the highest zooplankton biomass was observed outside the pumping station (Xidatian). Here the total biomass was about 2.7 times higher than in Erdiar. This is probably caused by the higher amount of food for zooplankton at Xidatian (cfr. Phytoplankton).

The characteristics of zooplankton in Lake Wuliangsuhai were the high species number of Rotifera and low species number of Protozoa and Copepoda. Most Cladocera species were only observed occasionally. Although as many as 32 species of zooplankton were observed in Lake Wuliangsuhai, the dominants were limited to a few species, such as *Ciliata*, *Brachionus angularis*, *Brachionus calyciflorus*, *Polyarthra trigla* and copepod nauplia. Some of the species are more or less littoral species (for example *Synchaeta tremula*, *Moina rectirostris* and *Alona guttata*). This seems reasonable because of the shallowness of the lake and the dense populations of submerged vegetation. Several of the species are characteristic for eutrophic conditions (for example *Cyclops vicinus*, *Filinia longiseta*, *Brachionus angularis*, *Brachionus calyciflorus*, *Trichocerca pusilla* and *Euchlanis dilatata*).

The number of zooplankton species in Lake Wuliangsuhai has decreased a lot as compared to the investigating results in 1982 (Tao Li 1983), especially species of Protozoa. In 1982, 67

species of zooplankton were observed. It seems reasonable to assume that the decrease in zooplankton species number mainly was related to deteriorating water quality of the lake, primarily the anoxic conditions during winter time.

Table 4.18 Zooplankton species list of Lake Wuliangsuhai

| Protozoa | Rotifera |
|---------------------------------------|---|
| <i>Ciliata</i> | <i>Asplanchna sp.</i> |
| <i>Diffugia elegans</i> | <i>Filinia longiseta</i> |
| <i>Cyxicidae</i> | <i>Brachionus angularis</i> |
| <i>Epistylis lacustris</i> | <i>Notholca acuminata var. quadrata</i> |
| <i>Cladocera</i> | <i>Branchionus urceolaris</i> |
| <i>Moina rectirostris</i> | <i>Brachionus calyciflorus</i> |
| <i>Diaphanosoma leuchtenbergianum</i> | <i>Polyarthra trigla</i> |
| <i>Alona guttata</i> | <i>Keratella cochlearis</i> |
| <i>Daphnia pulex</i> | <i>Chromogaster</i> |
| <i>Bosmina longirostris</i> | <i>Lecane lunaris</i> |
| <i>Daphnia carinata</i> | <i>Testudinella patina</i> |
| <i>Copepoda</i> | <i>Synchaeta tremula</i> |
| <i>Cyclops vicinus</i> | <i>Lepadella ovalis</i> |
| <i>Cyclopoida cop.</i> | <i>Euchlanis dilatata</i> |
| <i>Nauplia</i> | <i>Trichocerca pusilla</i> |
| | <i>Pedalia fennica</i> |
| | <i>Schizocerca diversicornis</i> |
| | <i>Keratella quadrata</i> |
| | <i>Ascomorpha sp.</i> |
| | <i>Collolheca sp.</i> |
| | <i>Brachionus capsuliflorus</i> |

Table 4.19 Zooplankton average biomass of Lake Wuliangsuhai in 2001 unit: mg/L

| Community Sampling point | Protozoa | Rotifera | Cladoera | Copepoda | Total |
|-----------------------------|----------|----------|----------|----------|-------|
| Xidatian | 0.83 | 0.62 | 0.21 | 16.65 | 18.3 |
| Erdiar | 0.27 | 0.16 | 0.43 | 5.93 | 6.8 |
| Average | 0.55 | 0.39 | 0.32 | 11.29 | 12.5 |

3.8.9 Reed and submerged vegetation

Species lists for reed and submerged vegetation in Lake Wuliangsuhai are given in the tables below. Reed covers large parts of the shallow areas of Lake Wuliangsuhai (see report from s-project 4, "Historical development"). This is dominated by *Phragmites australis* and *Typha* spp. The maximum depth at the edge of the reed belts was found to be 1.2 m. The by far most dominating species of submerged vegetation is the *Potamogeton pectinatus*. Also a number of

other species e.g. of the genera *Ceratophyllum* and *Chara* are abundant. Only at the deepest areas of “open water” in the lake are the bottom not covered with submerged vegetation.

Table 4.20 Reed species of Lake Wuliangsuhai

| | | |
|------------|-------------------------------|----------|
| Gramineae□ | <i>Phragmites australis</i> □ | dominant |
| Typhaceae□ | <i>Typha latifolia</i> □ | dominant |
| | <i>Typha minima</i> □ | rare |

Table 4.21 Submerged plant species of Lake Wuliangsuhai

| | | |
|------------------------|------------------------------------|----------|
| <i>Potamogeton</i> □ | <i>Potamogeton pectinatus</i> □ | dominant |
| | <i>Potamogeton nulaimus</i> □ | rare |
| | <i>Potamogeton perfoliatus</i> □ | extinct |
| | <i>Potamogeton zosterifolius</i> □ | extinct |
| | <i>Potamogeton crispus</i> □ | rare |
| <i>Najadaceae</i> □ | <i>Najas majos (flexilis)?</i> □ | rare |
| <i>Characae</i> □ | <i>Chara sp.</i> □ | rare |
| <i>Haloridaceae?</i> □ | <i>Myriophyllum spicatum</i> □ | common |
| | <i>Ceratophyllum oryzetorum</i> | common |

Submerged vegetation covers a major part of the lake bottom between 1.0 and 2.0 m depth. Above 1.0 m depth the lower cover of submerged vegetation is probably due to wave action and grazing by birds. Below 2.5 meters most observations were without plants. Light is probably a limiting factor at these depths.

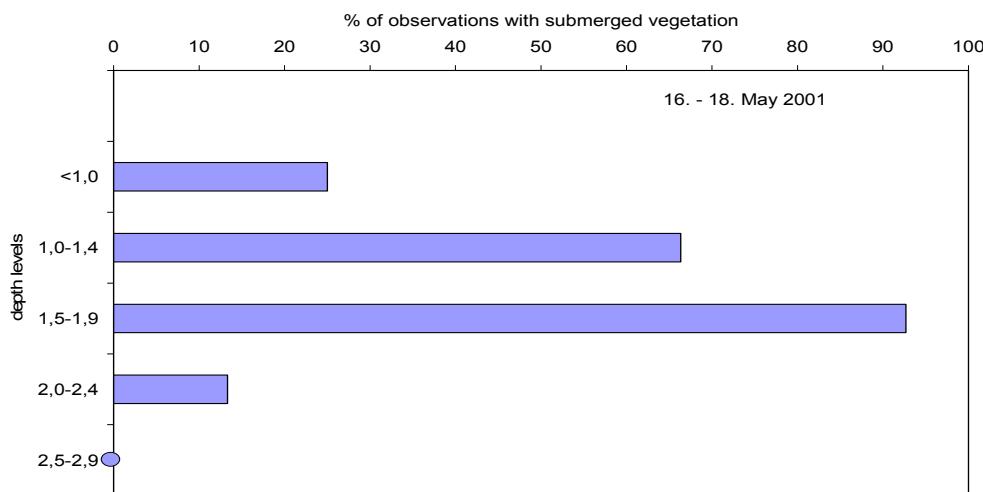

Figure 4.37 Fraction of 111 observations in different parts of Lake Wuliangsuhai with submerged vegetation on different depths at 16.-18- May 2001. The depths are adjusted to represent annual normal water level (1018.5 m above sea level.)

3.8.10 Fish

Fish species and quantity

The investigation results of fish species in Lake Wuliangsuhai are given in the following table. According to the investigation of the lake for fish in 2000, there are about eight species

belonging to two orders and three families. Among the eight species in the lake, five species are members of *Cyprinidae* two species belong to *Cobitidae* and one species is member of *Siluridae*. This investigation result shows that the fish species of the lake has been reduced by more than 60 % as compared to the investigation results of three times before. Some species such as Black Carp, Grass Carp, Amur Ide and High-eyes have disappeared. Now more than 80% of the fishes in the lake is Golden Carp, second is Stone Moroke and Mirror Carp. Others are few. Deteriorating water quality and primarily the anoxic conditions during winter is probably the main reason why the fish biodiversity have been markedly reduced in later years.

Table 4.22 Presence of different fish species in the lake

| | English name | Scientific name | Time of investigation (year) | | | |
|-------------------------|----------------------------|--|------------------------------|------|-----------|------|
| | | | 1960 | 1980 | 1981-1983 | 2000 |

| 17 | Loach | <i>Misgurnus anguillicaudatus</i> (Cantor) | + | + | + | + |
| 18 | Common Loach | <i>Barbatula posteroventralis</i> Nichols | + | + | + | |
| 19 | Common Loach | <i>Barbatula toni</i> (Dyb) | | | + | |
| 20 | Amur Catfish | <i>Silurus asotus</i> (L.) | + | + | + | + |
| 21 | Bullhead Catfish | <i>Pseudobagrus fulvidraco</i> (Richardson) | | | + | |
| 22 | High-eyes, Japenese Medaka | <i>Oryzias latipes</i> (Temminck et Schlegel) | | | + | |
| 23 | Spined sleeper | <i>Hypseleotris swinhonis</i> (Gunter), <i>Micropercops swinhonis</i> (Günther, 1873) | | + | + | |
| 24 | Goby | <i>Rhinogobius cliffordioppei</i> (Nichols) | | + | + | |
| Total number of species | | | 12 | 18 | 21 | 8 |

In the fish distribution of fresh water Lake Wuliangsuhai belongs to Hetao basin sub-region of Nin Mong plateau region. The fish distribution of this sub-region is old and the number of fish species is poor. The fish species of Lake Wuliangsuhai consist of three distribution systems: that of rivers and plains in China, that of early stages of the late third period and that of the Northern Plain.

The compound system of distribution of river and plain

In the lake Obtuse-head Bread and Silver Carp belong to this compound system, these two species taking up 25% of the total species number. Obtuse-head Bread and Silver Carp were southern fish species of introduction and now a small number of them live in the lake.

The compound system of distribution of early stage of the late third period

In the lake there are Mirror Carp, Golden Carp, Stone Moroke, Spiny Loach and Amur Catfish which belong to this compound system, these species taking up 62.5% of the total species number. Among these species, Mirror Carp and Golden Carp are major economic fishes and can live in both rivers and lakes. These species can form large biomasses in lakes.

The compound system of distribution of Northern Plain

In the lake there is one fish species of Loach which belongs to this compound system, this species taking up 12.5% of the total species. This is a small fish of less economic value. Today in Lake Wuliangsuhai Loach could hardly be seen. In general, the fishes of this compound system characters cold-resistant and basic-resistant etc.

Table 4.23 The components of fish distribution in Lake Wuliangsuhai

| Total of freshwater fish species | Numbers of the fish species of various compound systems and percent of total species number | | |
|----------------------------------|---|---|--|
| | The compound system of distribution of northern plain | The compound system of distribution of early stage of the late third period | The compound system of distribution of river and plain |
| 8 | 1(12.5%) | 5(62.5%) | 2(25%) |

Development of the fish population

So far Lake Wuliangsuhai has been formed for more than 100 years. Before the year 1954, fishes in the lake propagated naturally and there were Mirror Carp, Golden Carp, Amur Ide, Buir Lake Bleak, Loach and Amur Catfish etc. in the lake. Among these species, Mirror Carp was superior in numbers. With the development of fishery, the number of fish species was increased gradually in the lake. In 1958, Black Carp, Grass Carp, Silver Carp, Big-head Carp were put into the lake to increase the fish harvest. Later, Obtuse-head Carp was also bred. But these fishes could not form a large population biomass for a variety of reasons. Moreover, the fish species and quantity of fish have changed a great deal as time goes on. According to previous investigations, in 1956, among the output of fish Mirror Carp was 90%, but in 1960, the number decreased to 50-60%. After year 1960, the percentage of Mirror Carp kept on decreasing in the output of fish. On the contrary, the percentage of Golden Carp increased sharply, from 50-60% in 1983 to 78% in 1999. Thus there was a reduction of other fishes during the period. In short, there have been changes in the fish population in the past 50 years because of environmental and economic reasons, and further changes are expected in the future. The table below lists changes in the fish species composition in Lake Wuliangsuhai.

Table 4.23 The changes of the fish population in Lake Wuliangsuhai, given as the percent of the total output represented by each species. The table also presents total output (tons).

| Percentage Fish species | Year/Output (t) | | | | |
|-------------------------|-----------------|-----------|-----------|----------|----------|
| | 1956/4245 | 1960/3575 | 1983/1090 | 1990/429 | 1999/883 |
| Mirror Carp | 90% | 50-60% | 15-20% | 10% | 0.8% |
| Golden Carp | | | 50-60% | 78% | 78% |
| Amur Ide | | | 10-20% | 12% | |
| Grass Carp | | | 1% | | |
| Stone Moroke | | | | | 14% |

3.8.11 Fish harvest statistics

Since 1954 there has been a considerable fishing activity in Lake Wuliangsuhai. The figure below shows the commercial output of fish in the lake. Total fish cates has varied in the range 300-3600 tons per year. In the period 1960-1974 there was a dramatic decline in total commercial fish catch in the lake. During the next ca. 10 years period fish cates increased markedly without reaching more than about one third of the high catches in the early 1960s. This was followed by a period with very low catches. During the 1990s the fish catches showed a slowly increasing trend. After fish prohibition in 2000 and 2001, the fish catches in 2002 reached a level comparable to that in the early 1960s. However, in 2003 there was a decrease to about 50% of the maximum catches.

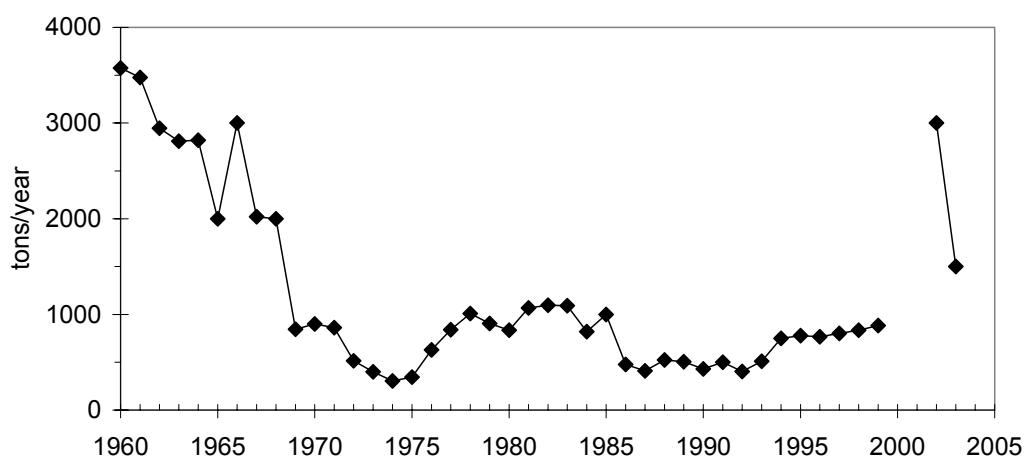

Figure 4.38 Total commercial fish catch in Lake Wuliangsuhai 1960-2003. In 2000 and 2001 fishing was prohibited

In the period 1981-1990 the fish catches was mainly composed by Golden carp, Mirror carp and Amut Ide. The latter species disappeared from the catches after 1991, and from 1994 Stone moroke was a newcomer. After the fishing prohibition in 2000 and 2001, Golden carp has been totally dominant in the catches.

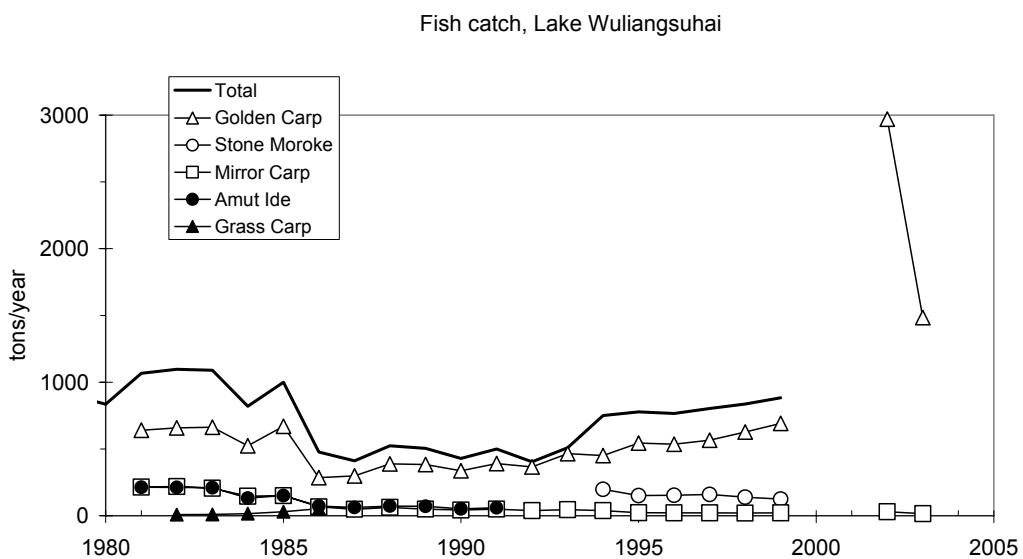

Figure 4.39 Commercial catch of different fish species 1981-2003. In 2000 and 2001 fishing was prohibited

3.9 Birds

Lake Wuliangsuhai attracts a high number of bird species both as a breeding area and as a stop-over on the migration to and from breeding areas further to the north. The low number of large freshwater wetlands and lake of this type in the region give Lake Wuliangsuhai a high importance for the bird migration in North Eastern parts of Asia. The quality of the lake is therefore of great concern that has been recognized by the authorities. The lake is a Bird Protection Area on the autonomous region level. The protection includes prohibition of hunting, egg collection etc.

Mrs. Qing (1996) has carried out a study on the birds of the Wuliangsuhai wetland (The avifauna of Wuliangsuhai Inner Mongolia, Inner Mongolia University Press). According to these data, 181 species of birds belonging to 16 orders, 45 families were recorded in the wetland of Wuliangsuhai, among which 97 species are breeding birds (including summer resident and resident), making up 54 % of the total species; 70 species of migrants, making up 39 %; 74 species of swimming birds and wading birds, making up 40 %. Among the 181 species, 5 species belong to the first kind of rare birds protected by the state. 25 species belong to the second kind of rare birds protected by the state.

During the survey in September 2000 more than 18.000 birds of 84 different species were observed. Eleven species not previously reported from the lake were identified. These include Red-necked grebe (*Podiceps grisegena*) Cattle egret (*Bubulcus ibis*), Steppe eagle (*Aquila nipalensis*), Avocet (*Recurvirostra avosetta*), Common greenshank (*Tringa nebularia*), Terek sandpiper (*Xenus cinereus*), Sanderling (*Calidris alba*), Ruddy turnstone (*Arenaria interpres*) Far eastern curlew (*Numenius madagascariensis*), Rock dove (*Columba livia*) and Richard's pipit (*Anthus richardi*).

In April 2004 more than 53.000 birds of 105 different species were counted and, after compensation for possible double counts, the number of counted individuals was still exceeding 32.000. Nine species, not previously reported from the lake, were identified and counted. These included Bean goose (*Anser fabalis*), Garganey (*Anas querquedula*), Merlin (*Falco columbarius*), Dunlin (*Calidris alpina*), Mew gull (*Larus canus*), Common swift (*Apus apus*),

Rosy pipit (*Anthus roseatus*), Isabelline shrike (*Lanius isabellinus*) and Great grey shrike (*Lanius excubitor*).

Together with bird species found during the autumn inventory in 2000, the number of identified bird species in these two inventories increased to 128, compared to the total number of 208. When reducing the observed number of individuals by contributions from possible double counts, the sum of the two inventory periods of migration at Lake Wuliangsuhai was approximately 42.000 individuals. The variety in bird species and great number of individuals emphasise the importance of the lake for the avifauna.

E

To protect bird life and species diversity it is important to maintain the present restrictions in accessibility to certain areas especially along the eastern shore of the lake. It is also essential to save a substantial area of reed during the winter for shelter to birds spending the winter at the lake and those arriving on migration before the new generation of reed has grown high enough to provide any shelter. Areas with dense submerged vegetation offer a substrate for nests of especially Whiskered Terns and White-winged Black Terns. Therefore such habitats have to be maintained. Several other suggestions for management measures to protect bird life are also presented in the report from the spring survey in 2004 (Svenson et al. 2004). The bird fauna at the lake fulfills criteria to become an internationally protected area according to the Ramsar convention, and the application to the convention would probably be one important tool to protect the bird life and habitat diversity.

The impression is that the lake attracts an increasing number of bird individuals and species. Intended restoration measures should be evaluated carefully with respect to intended and unintended effects on the avifauna. The protection status needs to be increased, and existing protective regulations should be better enforced.

APPENDIX

Presentation of Data

Canal Chemistry

Water Quality classification (selected variables)

Main ions in canals 1997-2002 (annual averages)

Organics and particles in canals 1997-2002 (annual averages)

Nutrients in canals 1997-2002 (annual averages)

Metals in canals 1997-2002 (annual averages)

Lake Chemistry

Lake water levels:

Daily water levels 1992-2002

Yearly water level 1960-1979

Meteorological data:

Air temperature Linhe 1975, 1995-2001

Precipitation Linhe 1975, 1992-2001

Wind speed Linhe 1975, 1992-2001

Water Quality classification (selected variables)
