Abstract

This report is part of the Norwegian contribution to OSPAR's Joint Assessment and Monitoring Programme (JAMP) of which of which OSPAR's Coordinated Environmental Monitoring Programme (CEMP) is based. JAMP 2006 included the monitoring of contaminants in sediment (10), blue mussel (52), dogwhelk (21), cod (10) and flatfish (10) along the coast of Norway from Oslo to Varangerfjord. The results showed elevated, in a few cases up to severely contaminated, levels of contaminants in the inner Oslofjord (PCBs, mercury and lead in cod; PCBs in blue mussel), and Sørfjord and Hardangerfjord (DDT, lead, cadmium and mercury in blue mussel; mercury and DDT in cod). The results from the remaining stations showed low or moderate levels of contamination in 2006. Considering the whole monitoring period (1984-2006), a significant upward trend was found for mercury in cod from the inner Oslofjord. A significant downward trend was found for lead in blue mussel from Sørfjord/Hardangerfjord. The "Pollution" index was between "moderate" and "marked", a level less polluted than in 2005. The "Reference" index was between "insignificant" and "moderate" as before. Contamination of organotin in blue mussel and imposex in dogwhelk were still apparent, however, there is some indication of downward trends. The results from studies using biological effects methods in cod are also discussed.

Foreword

This report presents the Norwegian national comments on the 2006 investigations for the Joint Assessment and Monitoring Programme (JAMP). JAMP is administered by the Oslo and Paris Commissions (OSPAR) and their Environmental Assessment and Monitoring Committee (ASMO). JAMP receives guidance from the International Council for the Exploration of the Sea (ICES). ASMO has delegated implementation of part of the programme to the Working Group on Concentrations, Trends and Effects of Substances in the Marine Environment (SIME). The Norwegian 2006 investigations are directed to particular JAMP issues relating to contaminants and implemented by SIME. JAMP replaced Joint Monitoring Programme (JMP) in 1995 and has been an integral part of OSPAR's Coordinated Environmental Monitoring Programme (CEMP) since 1998.

The Norwegian JAMP for 2005 was carried out by the Norwegian Institute for Water Research (NIVA) by contract from the Norwegian Pollution Control Authority (SFT), (NIVA contractO-6, O-26106, O-27106).

The Norwegian contribution to the JMP/JAMP was initiated by SFT in 1981 as part of the national monitoring programme. It now comprises three areas: the Oslofjord and adjacent areas (Hvaler-Singlefjord area and Langesundsfjord, 1981-), Sørfjord/Hardangerfjord (1983-84, 1987-) and Orkdalsfjord area (1984-89, 1991-93, 1995-96, 2004-05).

Since the North Sea Task Force Monitoring Master Plan was implemented in 1990, additional areas have also been monitored. These include: Arendal, Lista and Bømlo-Sotra areas. On the initiative of SFT and NIVA "reference" or merely diffusely contaminated areas from Bergen to Lofoten have been monitored since 1992 and from Lofoten to the Norwegian-Russian border from 1994.
+

***Reader's guide**. There is currently no OSPAR agreement as to the format for comments, however, to maintain consistency and completeness the Norwegian contribution is presented in accordance with the earlier agreed standardised format (ASMO 1997, Annex 12). Following the SIME meeting in Edinburgh, 11-13 February, 2008, the full report in PDF-format can be downloaded from either of two websites: the SFT's website and using SFT's TA-number at http://www.sft.no/publikasjonerforside____10990.aspx or from NIVA's website at http://www.niva.no/symfoni/infoportal/portenglish.nsf and doing a search on the "løpenr", which is the NIVA-report number for this report.*

***Acknowledgments.** Thanks are due to many colleagues at NIVA, especially: Lise Tveiten, Merete Schøyen, Åse Kristine Rogne, Sigurd Øxnevad, Jarle Håvardstun, for field work, sample preparations and data entry; Alfhild Kringstad,Olav Bøyum, Torgunn Sætre, and their colleagues for organic analyses; Bente Hiort Lauritzen and her colleagues for metal analyses; Randi Romstad and her colleagues for biological effects measurements, Gunnar Severinsen, Ling Shi and Tore Høgåsen for data programme management and operation; and to the authors Anders Ruus (biological effects methods), Mats Walday (organotin), and Eva Hagebø and her colleagues (analytical quality assurance). Thanks go also to the numerous fishermen and their boat crews for which we have had the pleasure of working with.*

Oslo, 25 December 2007.

1. General Details

1.1. Executive Summary / Sammendrag

The Norwegian JAMP 2006 included the monitoring of micropollutants (contaminants) in sediment (10 stations), blue mussel (52 stations), dogwhelks (21 stations), cod (10 stations) and flatfish (10 stations) from Oslo in the south-east along the coast of Norway to the Varangerfjord in the north-east. The mussel sites include supplementary stations for the Norwegian Index programme, The results showed several cases of elevated levels of contaminants, i.e. higher than Class I (*insignificantly*[1] polluted) in the Norwegian Pollution Control Authority's (SFT's) classification system (or over provisional “high background”). The major cases were found in:

- Part of JAMP area 26 - Oslofjord was contaminated with PCBs and to a lesser extent mercury and lead. In particular cod liver from the inner Oslofjord was *markedly* polluted with PCB (Class III). A significant downward trend was found for PCBs in blue mussel from the inner Oslofjord. A significant upward trend was found for mercury in cod fillet from both "large" and "small" individuals and for cadmium in cod liver from the inner Oslofjord 1984-2006;
- JAMP areas 63 and 62 - Sørfjord and Hardangerfjord was contaminated with DDT, lead and cadmium. Blue mussel was up one class to *extremely* polluted (Class V) with DDT, and as before, *markedly* polluted with lead and cadmiumCod, was *moderately* polluted (Class II) with mercury and DDT, as before. A significant downward trend was found for lead in blue mussel at one station in Hardangerfjord 1987-2006, and also for cadmium at three stations in Sørfjord over the same period.
- Part of JAMP area 26 – Langesundsfjord has been an area of concern partly due to elevated concentrations of HCB in blue mussel. In 2002, 2003, 2004 and 2006 the blue mussel was *insignificantly* or *moderately* polluted (Class I and II). In 2005 the blue mussel were *markedly* polluted. A downward trend was found for the period 1990-2006.

Two environmental indices have been applied annually since 1995 to assess the levels of contamination in blue mussel from “polluted” and “reference” areas. In 2006 the Pollution Index result was between *moderate* and *marked* (class II-III). This was one level down compared to 2005. The Reference Index was between *insignificantly* and *moderately* polluted (Class I-II), as before.

The biological effect parameters OH-pyrene (pyrene metabolite; marker for PAH exposure), δ-aminolevulinic acid dehydrase (ALA-D; marker for lead exposure), and cytochrome P4501A (EROD-activity; marker for planar hydrocarbons, such as certain PCBs/PCNs, PAHs and dioxins) were determined in cod from four stationsalong the coast from the Oslofjord, Karihavet and Sørfjord. In 2006, the Oslofjord showed the highest levels of OH-pyrene and EROD-activity. With regard to EROD-activity, the same result has been obtained in some, but not all, of the preceding years. The amount of CYP1A protein was however consistently higher in the Oslofjord than the Sørfjord and the Karihavet, 2003-2006. Results for ALA-D indicated exposure of cod to lead in the inner Oslofjord and inner Sørfjord.

The presence of organotin (TBT) in Norwegian waters was still a problem in 2006, most evident close to harbours, but also at stations remote from known point-sources. Concentrations of organotin were elevated in blue mussel and dogwhelk, and biological effects from TBT were found in dogwhelk from all eight stations except for one. Eight of the twelve timeseries for TBT in blue mussel 1997-2006 showed significant downward trends. There was also a downward trend in effects of TBT in dogwhelk found at three stations. These results may be an indication that regulatory action has lead to an improvement in the investigated areas.

[1] Corresponds to Norwegian term *ubetydelig*, and has no statistical implications in this context.

Sammendrag

*JAMP (*Joint Assessment and Monitoring Programme*) er et internasjonalt program for miljøovervåking av kystfarvann. Norge er et av tolv land som gjennom Oslo-Pariskonvensjonen (OSPAR) har forpliktet seg til å delta i dette felles overvåkingsprogrammet. Programmet i Norge startet i 1981 og hovedmålsettingen er å overvåke miljøgifter i påvirkede områder og ellers langs hele norskekysten. Resultatene fra de minst påvirkede områdene benyttes for å angi "bakgrunnsnivåer". Resultatene rapporteres årlig.*

I 2006 omfattet JAMP undersøkelse av sediment (10 stasjoner), blåskjell (52, inkludert de til SFTs forurensningsindeks og til overvåking av TBT), purpursnegl (21 stasjoner), torsk (10 stasjoner) og flatfisk (10 stasjoner) langs kysten fra Oslofjorden til Varangerfjorden . Resultatene tydet på forhøyede konsentrasjoner av miljøgifter, dvs. mer enn Klasse I i SFTs klassifiseringssystem, eller over antatt "høyt bakgrunnsnivå". Disse tilfellene ble registrert i:

- *Oslofjorden med inntil Kl.III for PCB og mindre forurenset med hensyn til kvikksølv og bly. Torskelever fra indre Oslofjord var markert forurenset med PCB (Kl.III). Det ble også funnet signifikant økende trender for kvikksølv i torskefilet fra både "store" og "små" individer og for kadmium i torskelever fra indre Oslofjord 1984-2006;*
- *Sørfjorden og Hardangerfjorden med opp til Kl.V for DDE og Kl.III for bly og kadmium i blåskjell, og Kl.II for kvikksølv og DDE i torsk. Det ble funnet en signifikant avtagende trend for bly i blåskjell på en stasjon i Hardangerfjorden 1987-2006, og for kadmium på tre stasjoner i Sørfjorden.*
- *Langesundfjorden har vært et område med bl.a. høye konsentrasjoner av HCB i blåskjell. Forurensningsnivået fra 2002 til 2004 og 2006 har vært ubetydelig eller moderat (Kl.I eller II), men i 2005 var blåskjellene markert forurenset (Kl.III). En avtagende trend ble funnet for perioden 1990-2006.*

SFTs blåskjell-forurensningsindeks og blåskjell-referanseindeks har blitt brukt årlig siden 1995 på en gruppe "forurensede-" og "referanse-" fjordområder. Forurensningsindeksen for 2006 viste ”moderat” til ”markert” forurensning. Dette var en lavere klasse en som i 2005. Referanseindeksen har klassifisert sin gruppe mellom ”lite” og ”moderat” forurenset i hele perioden.

Følgende biologiske effekt-parametre ble undersøkt i torsk fra tre-fire stasjoner langs kysten fra indre Oslofjord til Hardanger: OH-pyren (pyren-metabolitt; markør for PAH-eksponering), δ-aminolevulinsyre dehydrase (ALA-D; markør for bly-eksponering), og aktivitet av cytokrom P4501A (EROD; markør for plane hydrokarboner, slik som spesifikke PCB/PCN, PAH og dioksiner). Oslofjorden viste de høyeste OH-pyren-nivåene. OH-pyren nivåene i indre Oslofjord var høyere en på de andre stasjonene. Resultatene for ALA-D indikerte bly-eksponering for torsk fra indre Oslofjord og indre Sørfjord. Høyest EROD-aktivitet ble observert i indre Oslofjord. Tidligere år har vist at EROD-aktivitet i fisk fra Oslofjorden og Sørfjorden ikke er konsistent høyere enn på andre, antatt mindre forurensede stasjoner, selv om dette er observert enkelte år. Derimot var mendgen CYP1A protein konsekvent høyere i Oslofjorden enn i Sørfjorden og Karihavet, 2003-2006.

Effekter av organotin (bl.a. TBT) kunne fortsatt registreres i 2006, tydeligst i havner eller i områder med mye skipstrafikk, men også på stasjoner som var antatt lite påvirket. Konsentrasjoner av TBT i blåskjell og purpursnegl var forhøyet, og virkning av TBT (imposex) ble registrert på samtlige stasjoner unntatt en. Åtte av tolv tidstrender for TBT i blåskjell perioden 1997-2006 var avtakende. Det ble funnet en signifikant nedadgående trend for imposex på tre stasjoner.Disse resultatene kan kanskje tyde på at forbud mot bruk av TBT som begroingshindrende middel på båter har ført til forbedring i de undersøkte områdene.

1.2. Introduction

The Norwegian contribution to the "Joint Assessment and Monitoring Programme (JAMP) was initiated by the Norwegian Pollution Control Authority (SFT) and is integrated with SFT's State Pollution Monitoring Programme. The procedures and practice of JAMP has also provided a basis for other investigations of interest to SFT but not necessarily requested by JAMP (e.g. SFT's Index Programme (Pollution and Reference Indices), chapter 1.3.8).

JAMP is administered by the Oslo and Paris Commissions (OSPAR) and since 1998, parts of JAMP have formed and integral part of OSPAR's Coordinated Environmental Monitoring Programme (CEMP).

Data are submitted to ICES using the integrated environmental reporting format 3.2.1 (www.ices.dk/env/repfor/), and screening using the their DATSU programme (www.ices.dk/datacentre/datsu/). The Norwegian JAMP data can be currently relevant to 4 purposes in the database: *temporal trends*, *spatial distribution*, *effects of hazardous substances*, and to a lesser degree the *risk to human health*. The former three are obligatory .

This report focuses on issues and situations in Norway concerning contaminants and considered of interest to the implementation of JAMP and CEMP (Table 1). It should be noted that these issues are being revised (cf., MON 2001).
The chapter structure of this report for the first and second level is according to an earlier agreed format (ASMO 1997, Annex 12) which *inter alia* presents results before methodology. No new format for reporting National Comments has been agreed by OSPAR, however, each country is obliged to ensure that their respective experts are as familiar as possible with the detail of their national submissions (ASMO 2007). In this regard, the format that of Norway has chosen for National Comments has served this purpose.

[1]) Certain Brominated Flame Retardents
[2]) Perfluoroctylsulfonate
[3]) Polychlorinated dibenzodioxins and furans
[4]) PAH- and Metal-Specific Biological Effects
[5]) General Biological Effects
[6]) From SIME 2004b:

AA-2 An assessment in 2010 of the quality status of the OSPAR maritime area and of its sub-regions.

HA-4 A more elaborated assessment by 2009 of biological effects of hazardous substances in the maritime area;

HA-5 An assessment by 2009 of temporal trends and (where relevant/feasible) spatial distribution for the hazardous substances where periodic sampling and analysis is undertaken, in particular under CAMP, CEMP and RID;

HA-6 A general assessment by 2009 of the development in the quality status of the maritime area in relation to hazardous substances that should take into account the results of the assessments under HA-1 and HA-5, HA-2 and HA-4 and HA-3, and the results of any screening of levels of substances in the marine environment covered by HM-3;

HM-3 When appropriate, identification of the likely impacts on the marine environment of substances recorded, inter alia, in source inventories, or identified by screening methods.

1.3. Information on measurements

An overview of JAMP stations in Norway is shown in the tables in Appendix E and maps in Appendix G. The stations and sample counts relevant to the 2006 investigations are noted in the tables in Appendix E. Data reports have been published recently for sediment 1986-2006, biota 1981-2006, biological effects (Shi *et al.* 2008).

Blue mussel was sampled at 52 stations (including supplementary stations for Index and TBT), dogwhelk at 21, cod at 10 , flatfish at 10 and sediment at 10 stations from the border to Sweden in the south to the border to Russia in the north. Generally, blue mussel are not abundant on the exposed coastline from Lista (south Norway) to the North of Norway. A number of samples were collected from dock areas, buoys or anchor lines.

This chapter focuses on the principle cases where *median* concentrations exceeded provisional "high background" ("normal"). The median concentration can be derived from the tables in Appendix I or figures in Appendix J, taking into consideration the year and whether the concentration is on a wet weight or dry weight basis. Where possible, these medians are classified according to the Norwegian Pollution Control Authority's (SFT's) **environmental quality classification system** (cf. Molvær *et al.* 1997). An extract of the system that is applied in this report is shown in Table 6 and Table 5 and includes unofficial conversion to other bases. The system does not cover all of the analysed contaminants for for all of the analysed species-tissues, however provisional "high background" concentrations have been determined and these are listed in Table 7. "High background" concentrations set the upper limit for Class I in SFT's system. The factor by which concentrations exceeded “high background” is termed **overconcentration**. "High background" concentration corresponds to the upper limit to Class I; “slightly” or “insignificantly” polluted, which in this context has no statistical implications. Below, the median concentrations are assessed according to the SFT system, but where this is not possible, overconcentrations are used. The term "significant" refers to the results of a statistical analysis of linear trends shown in Appendix I. More details concerning these terms and methods can be found in chapter 2.1.2.

1.3.1. Oslofjord area

Blue mussel from the inner Oslofjord were moderately polluted with ΣPCB-7 (SFT's Class II, Figure 1A). Cod liver from the inner Oslofjord was markedly polluted with ΣPCB-7 (Class III, Figure 2A). The median concentration in cod liver was 3550 µg/kg w.w., about 15% lower than the 2005 value which was the highest recorded median concentration since JAMP-monitoring started in 1990. Nearly all the cod collected during this period have been collected in the Vestfjord area west of Steilene. The range found in 2006 was 219-7409 µg/kg w.w. The fillet from the same fish were moderately polluted with ΣPCB-7 as it has been since 2000 (Class II, Figure 2C). Cod liver and fillet from the outer Oslofjord was moderately polluted with regard to ΣPCB-7 (Færder, st.36B, Figure 2B).

In 1994, and renewed in 2005, the Norwegian Food Safety Authority (*Mattilsynet*, earlier referred to as SNT) advised not to consume liver of cod from the inner Oslofjord (north of Mølen - st.35A, see Map 1 in Appendix G) due to concerns about PCB contamination (cf. Table 3).

A significant linear *downward* trend was detected (see method description in chapter 2.1.3) for ΣPCB-7 in blue mussel from the inner Oslofjord (30A and 31A Figure 1A, B) for the period 1988 to 2006.

Power analyses (see chapter 2.1.3) indicated that a hypothetical trend of 10% change per year in ΣPCB-7 concentration in the blue mussel from the mid and inner Oslofjord would take 12 to 14 years to be detected with 90% significance (Appendix I).

The fillet of "small"[1] (42-48 cm) and "large" cod (50-78 cm) from the inner Oslofjord in 2006 were moderately polluted with mercury; second and third highest since monitoring started in 1984 (Class II, Figure 3A, B). A significant *upward* trend was detected for the period 1984-2006 for both size groups. No significant trend was found for the period 1998-2006. Considering the entire period, the power, indicated as number of years to detect a hypothetical 10% change per year for mercury in cod fillet from either station, was slightly better for "small" fish (11 years) than "large" fish (13 years) (cf. Appendix I). Concentrations of mercury were significantly higher in "large" cod compared to "small" cod.

Median concentration of lead in cod liver from the inner Oslofjord (30B) 2006 was 0.1 mg/kg w.w.. This was less than the concentration found in 2005 and a fifth of the 2002 value; the second highest found during the entire period (1990-2006). "High background" for this metal is 0.1 mg/kg w.w. Blue mussel from one station in the inner Oslofjord (st. 30A) were moderately polluted with respect to lead in 2006.

The SFT's environmental quality classification system does not include cadmium and lead in cod liver.

It should be noted that the Index programme indicated moderate concentrations of TBT in blue mussel from a station located in the inner Oslofjord (see chapter 1.3.8).

[1] The size of "small" and "large" cod depends on the station-year catch, and hence may vary (see section 2.1.3. The range given is the lower and upper quartile of the median lengths of the "small" or "large" fish.

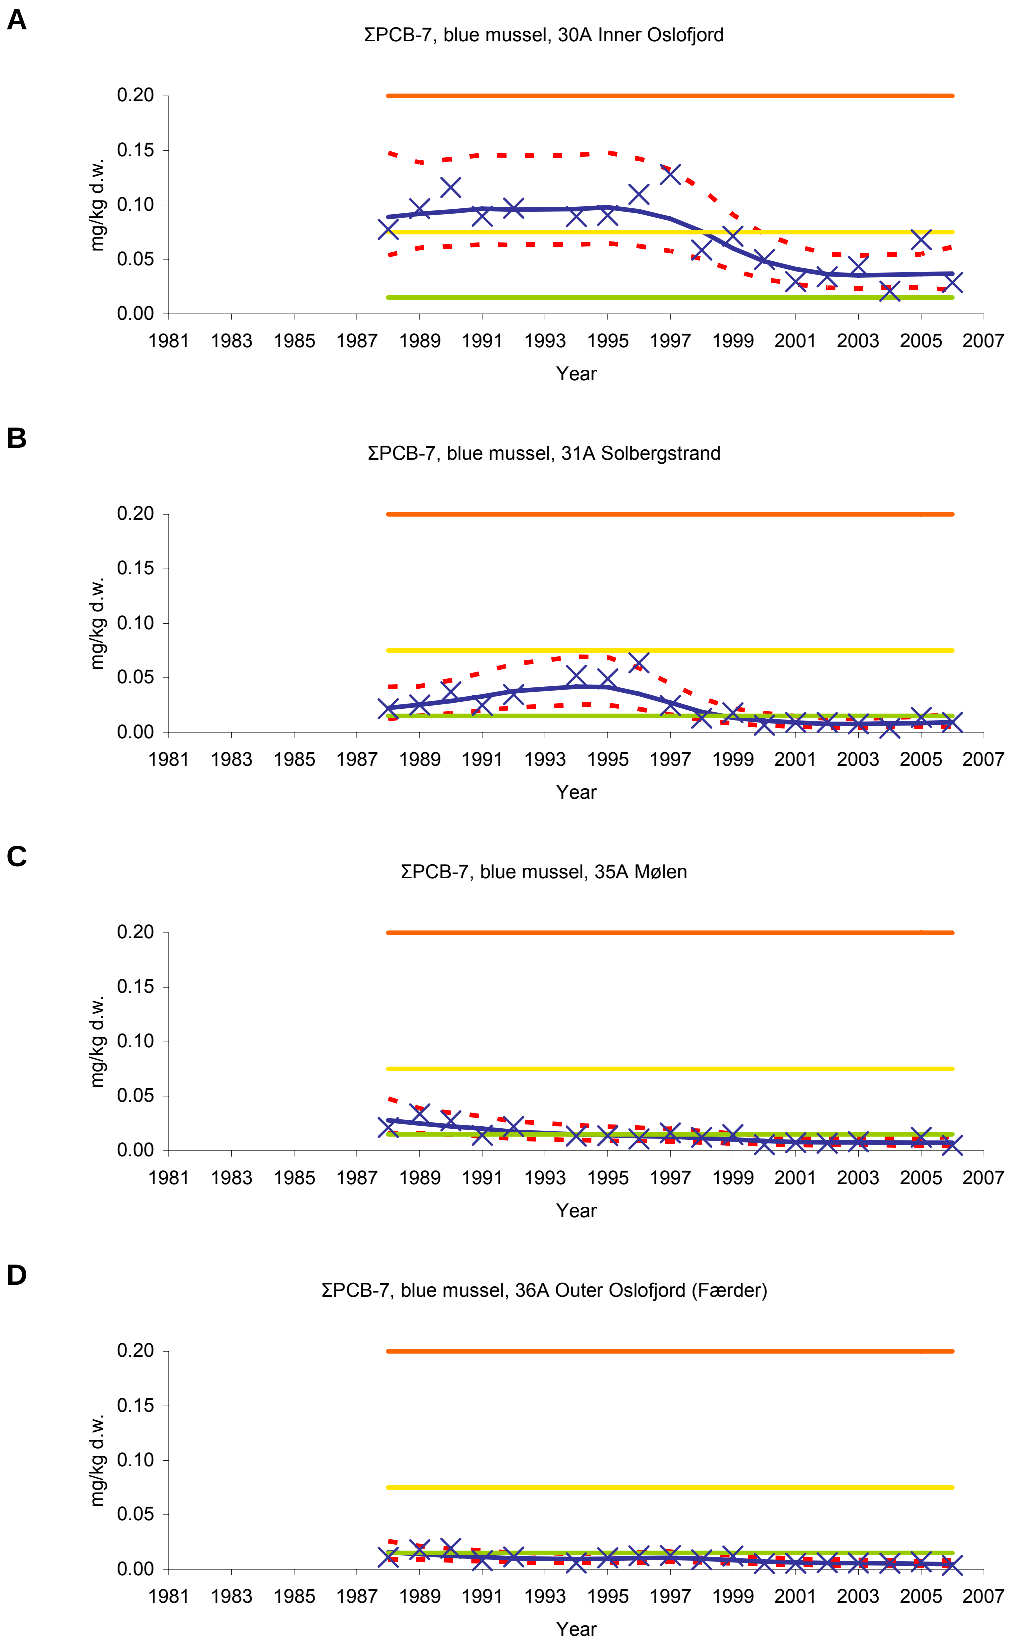

Figure 1. Median ΣPCB-7 (sum of PCB 28, 52, 101, 118, 138, 153 and 180) concentration in blue mussel (*Mytilus edulis*) from inner (st.30A) to outer (st.36A) Oslofjord. (cf. Appendix G and Appendix I, and and key in Figure 21).

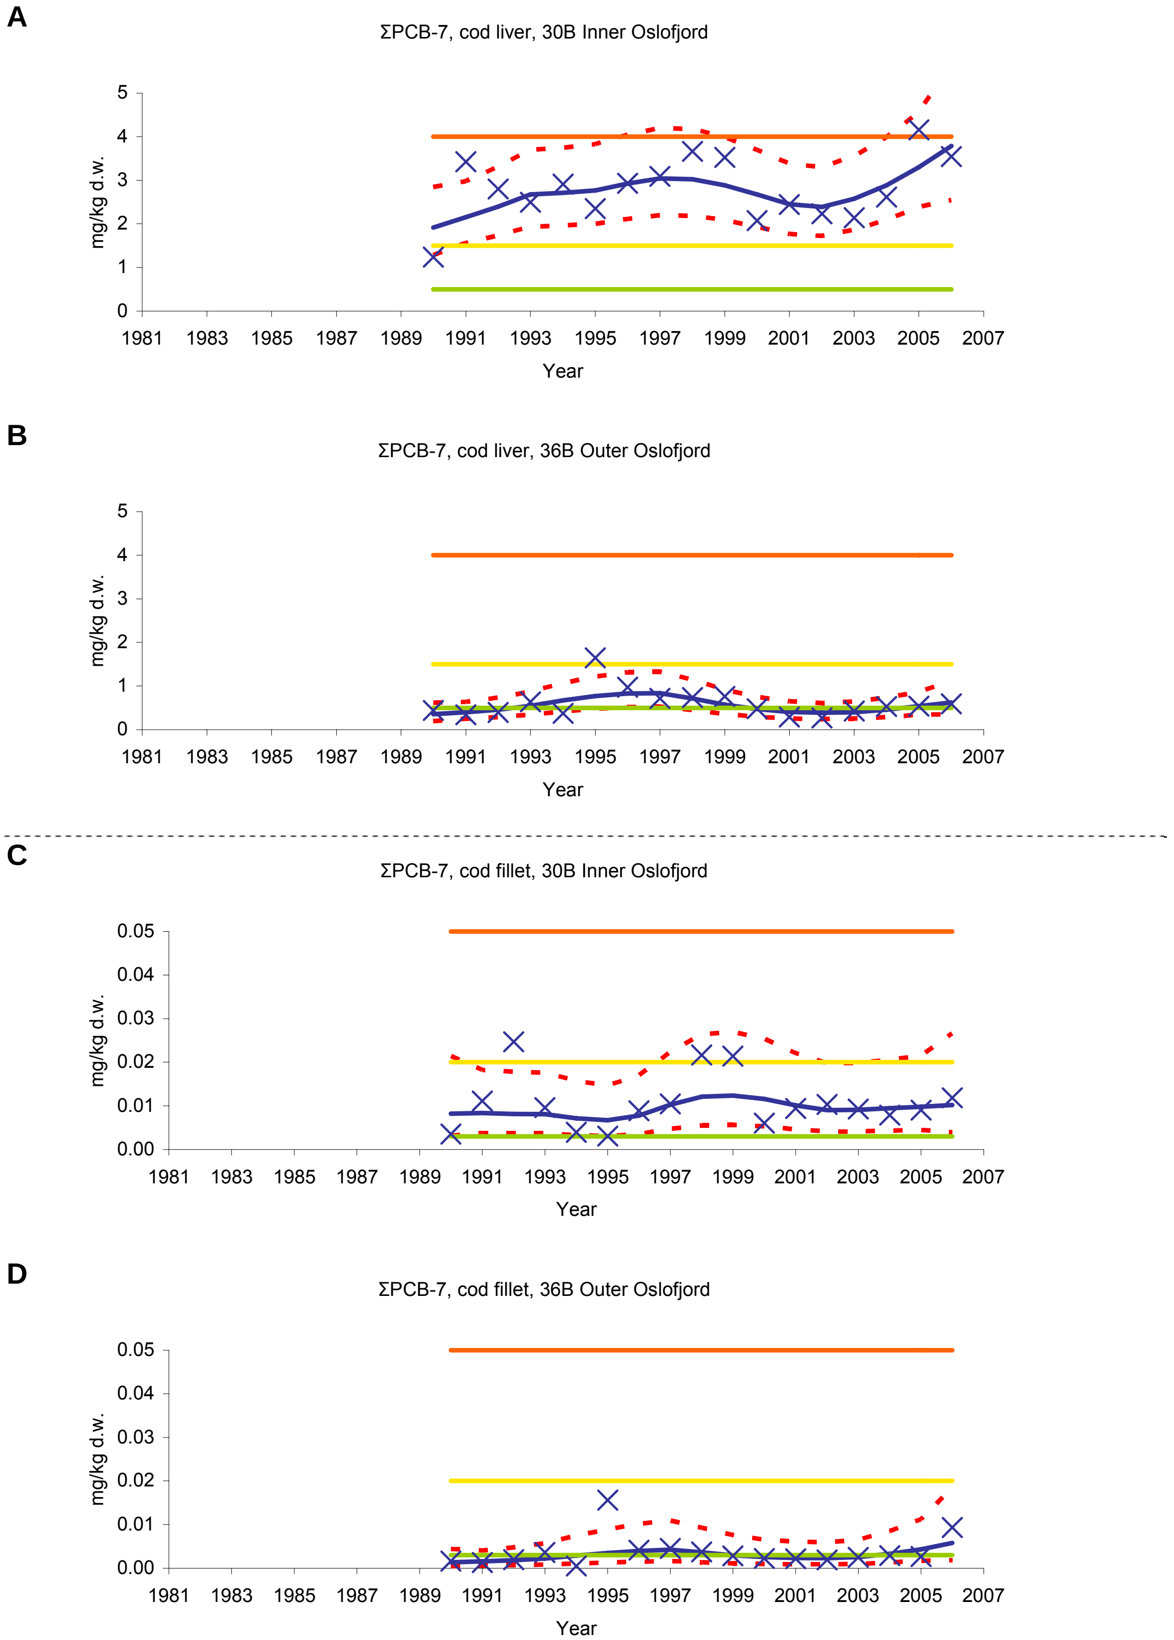

Figure 2. Median ΣPCB-7 (sum of PCB 28, 52, 101, 118, 138, 153 and 180) concentration in liver and fillet of cod (*Gadus morhua*) from the inner (st.30B) to outer (st.36B) Oslofjord. (cf. Appendix G and Appendix I, and key in Figure 21).

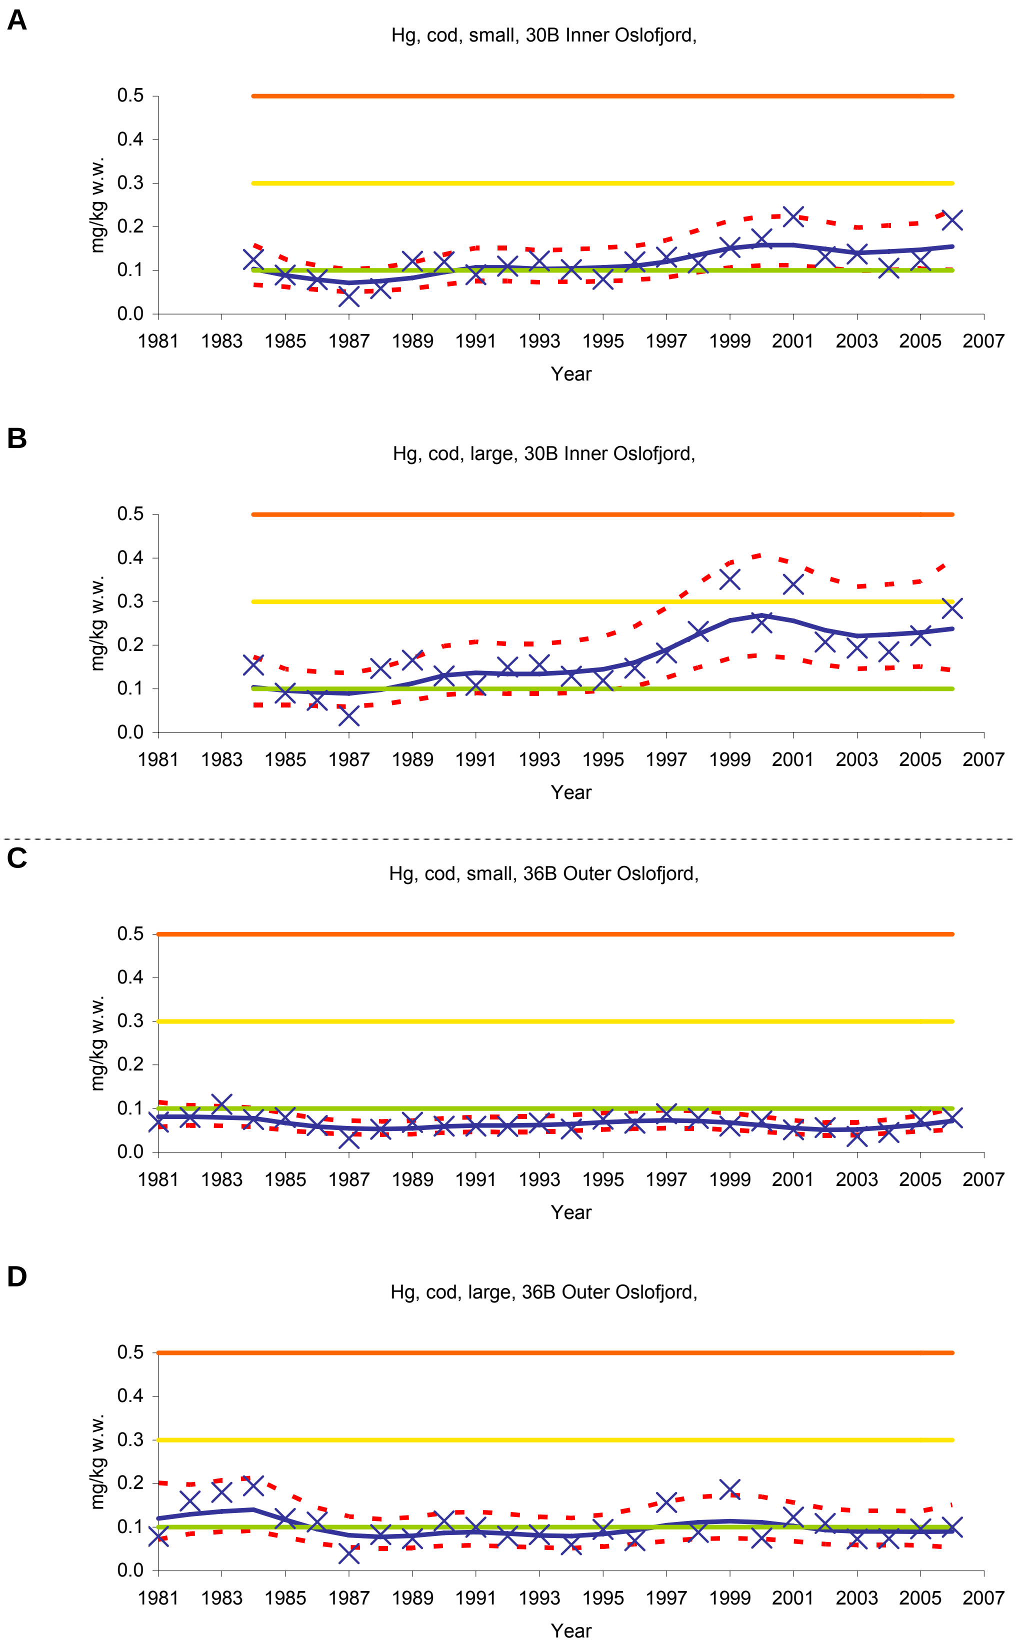

Figure 3. Median mercury (Hg) concentration in fillet of cod (*Gadus morhua*): for the inner Oslofjord (st.30B) “small” (**A**) and “large” (**B**) fish, and for the outer Oslofjord (st.36B) “small” (**C**) and “large” (**D**) fish. (cf. Appendix G and Appendix I, and key in Figure 21).

Blue mussel from Langesundsfjord (st.71A) in 2006 were moderately polluted with HCB (Class II, Figure 4A). The median concentration for 2006 was 1.27 mg/kg dry weight, about a third of the relatively high median found in 2005 which was the highest since 1991. Median values found at two nearby Index stations (I712 and I713) were markedly polluted (Class III), but also lower i 2006 compared to 2005 (Figure 4B and C). Concentrations have varied greatly since 1983 but median values have decreased distinctly since 1989 (Figure 4) due to about 99% reduction in discharge of HCB and other organochlorines from a magnesium factory (cf. Knutzen *et al.* 2001).

The power of the monitoring programme was 19 years for the period 1990-2006 and more than 25 years for the entire period (cf. Appendix I). The 1983-2006 data series had a significant *downward* trends and also a significant *downward* trend was found for the recent period (1990-2006).

It should be noted that dioxin is one of the contaminants monitored to establish the Pollution Index (see section 1.3.8). Dioxin toxicity equivalents based on the Nordic model (TCDDN) showed that the blue mussel was severely polluted (SFT Class IV) at Langesund (st. 71A) and extremely polluted at one nearby Index station (I712), whereas the other Index station, and closest to Frierfjord, (I713) was markedly polluted (Figure 35).

Appendix G and Appendix I, and key in Figure 21). Vertical line indicates when a magnesium factory reduced it's discharge by 99%. **NB: log-scale.**

1.3.2. Sørfjord and Hardangerfjord

The development of the contaminant conditions in these connected fjords and the main remedial actions that have been taken, have been outlined in the JAMP National comments for 1989 (Green 1991) and in recent reports concerning Sørfjord in particular (Skei 2000, 2001, Skei & Knutzen 2000, Skei *et al.* 1998). The results from JAMP 2006 are coupled to other studies in this area (cf. Knutzen & Green 2001a, Ruus & Green 2002, 2003, 2004, 2005, 2006, 2007) and confirm that the Sørfjord, and in some cases also Hardangerfjord, continue to be contaminated especially with cadmium (Figure 5), lead (Figure 6), mercury (Figure 7 and Figure 8), ppDDE (Figure 9, Figure 10 and Figure 11), and to a lesser extent PCB (Figure 11).

In 2002 the Norwegian Food Safety Authority (*Mattilsynet*, earlier referred to as SNT) extended their advice against the consumption of blue mussel to include all seafood in the Sørfjord including deep-water fish due to concerns about metal and PCB contamination (Table 3).

Results for blue mussel collected from the Sørfjord indicated that these were moderately (Class II) or markedly polluted (Class III) with cadmium in respect to SFT's classification system (Figure 5, Appendix I). Blue mussel as far as Vikingneset (st.65A. ca.84 km from Odda at the head of the Sørfjord) were moderately polluted with cadmium (Figure 5). A significant *downward* trend was found for cadmium at three stations in Sørfjord (st.52A, 56A and 57A) and two in Hardangerfjord (st.63A and 65A) (Appendix I). Also, the median lead concentration at the station nearest Odda (st.51A) and at Kvalnes (st.56A), about 15 km distant, were markedly polluted (Class III), whereas the other two stations in the Sørfjord (st.52A and 57A) and the two nearest stations in the Hardangerfjord (st.63A and 65A) were moderately polluted. A *downward* trend was found for lead at Ranaskjær (st.63A), 1990-2006. Three stations in Sørfjord were moderately polluted with respect to mercury.

Cod fillet from “small” (35-41 cm) and "large" individuals (42-55 cm) from the inner Sørfjord (st.53B) were moderately polluted with mercury (Class II). Overconcentrations were found for cadmium in cod liver from inner Sørfjord (2 times). It was not feasible to collect flounder from the inner Sørfjord, however, flounder caught in the adjacent Hardangerfjord had no overconcentrations.

The power of the sampling strategies for blue mussel was relatively poor for samples collected from Odda; the innermost part of Sørfjord (st.51A or 52A). For example for lead in blue mussel from these stations, it is estimated that it would take 19-22 years to detect a hypothetical trend of 10% per year with 90% significance (Appendix I). This reflects the large variability found in the data series from this area. The variability is mostly due to the irregular/accidental input of contaminated discharges. The power improved with distance from Odda, and at Ranaskjær (st.63A) and Vikingneset (st.65A) it was only 13 years.

Blue mussel at Kvalnes (st.56A) in the mid Sørfjord region were extremely polluted with ppDDE (Class V); with a median concentration of 186 µg/kg d.w.. The lower limit to Class V is 150 µg/kg d.w.. Blue mussel at the mouth of the Sørfjord, Krossanes (st.57A) about 20 km to the north, was moderately polluted (Class II, Figure 9 and Figure 10). Cod liver from the Sørfjord was moderately polluted with ppDDE (Figure 11A, Appendix I).

The liver of cod from Hardangerfjord for 2006 were insignificantly polluted (Class I) with respect to ΣPCB-7. Since JAMP monitoring started in the Sørfjord and Hardangerfjord the median values have varied between 100 and 2400 µg/kg w.w. (Appendix I). This indicated that cod is subject to a variable exposure from PCB, but the cause of this variation is not clear.

No trends were evident for ppDDE and ΣPCB-7 in blue mussel and cod.from inner Sørfjord where 2006 median were in Class II or higher.

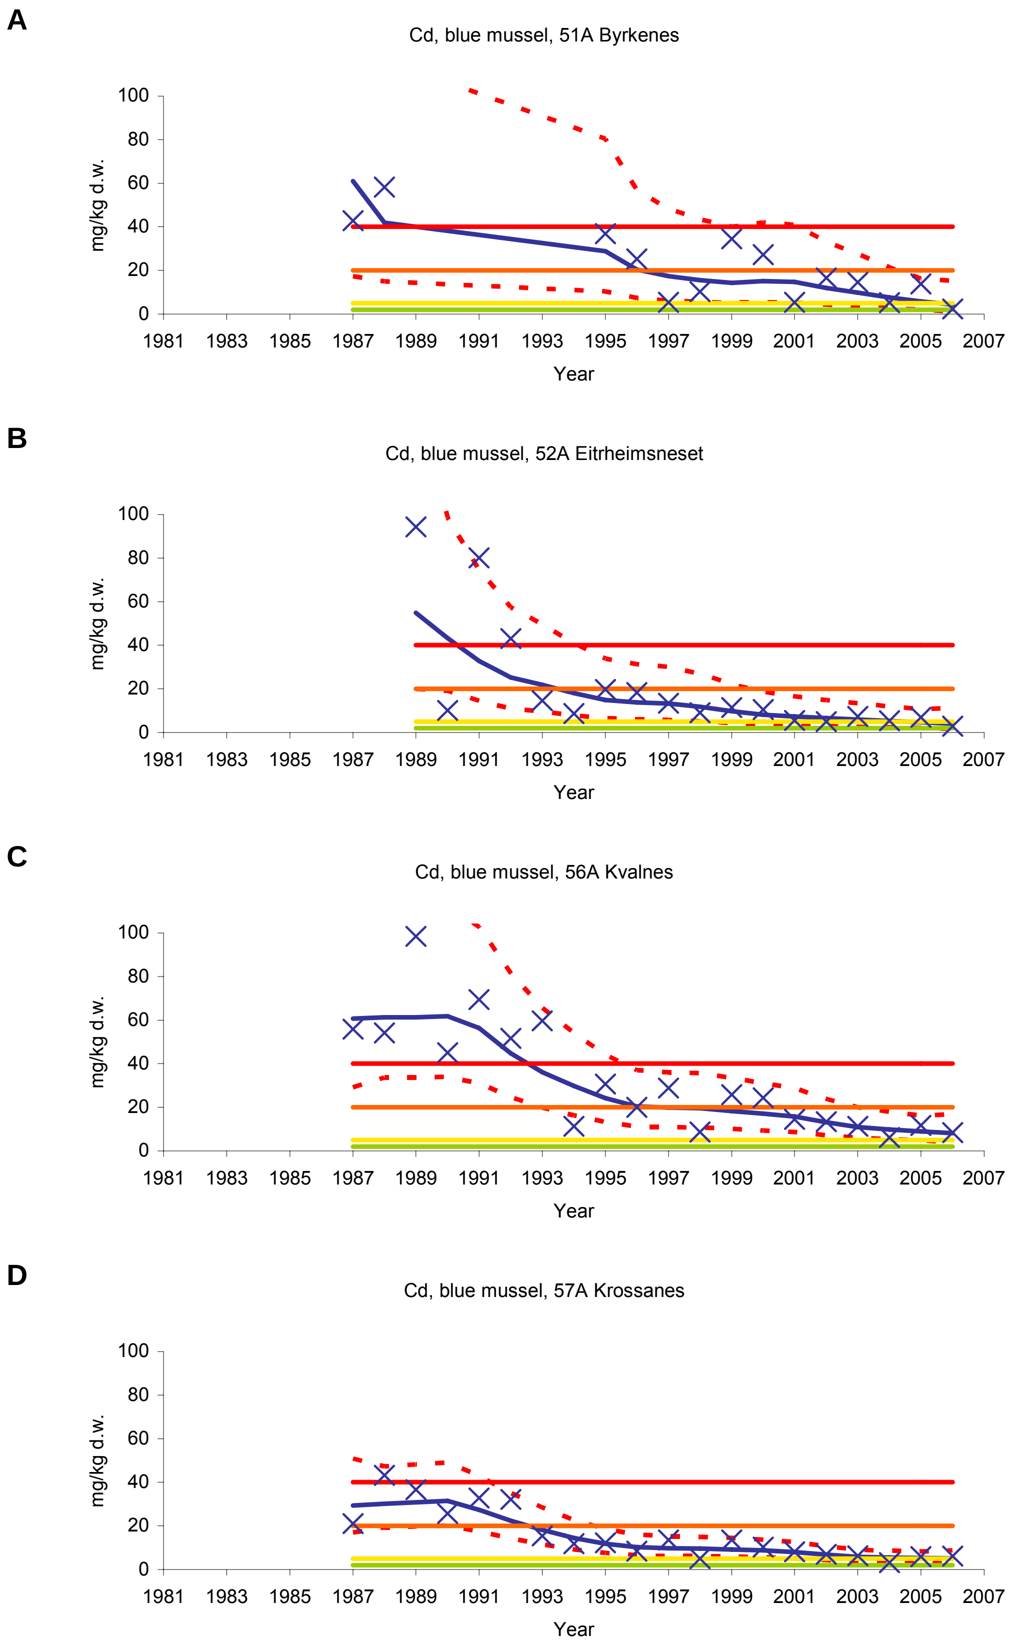

Figure 5. Median cadmium (Cd) concentration in blue mussel (*Mytilus edulis*) from inner (st.51A) to outer (st.57A) Sørfjord. NB: (cf. 1.3.3. Lista area

Blue mussel, cod and dab were insignificantly polluted (Class I or below provisional high background), with the exceptions of cadmium in dab liver and mercury in “large” dab which were moderately polluted in 2006. No upward trends were found (st.15, Appendix I and Appendix J).

1.3.4. Bømlo-Sotra area

It was impractical to continue sampling for flatfish at Borøyfjorden (st.22F). Thus, a new station in Åkrafjorden, Kyrping (st.21F), was initiated in 2000. This station is located about 82km south-east of Borøyfjorden, but like this fjord, Kypring is located in a reference area.

Blue mussel, cod and flounder from this area (22A, 23B, 21F) generally were only insignificantly polluted (Class I) or showed no overcentrations with respect to metals or organochlorines with the exception of cod fillet which was moderately polluted with mercury (Class II, Appendix I and Appendix J).

1.3.5. Orkdalsfjord area

Blue mussel from this area were monitored for the period 1984-1996, and then not again until 2004-2005 when bulk samples from four stations were investigated (Trossavika – st.84A, Flakk – 82A or Ingdalsbukt – 87A).

1.3.6. Open coast areas from Bergen to Lofoten

This stretch of coastline covers 7° of latitude to 68°N (Appendix G). Sixteen mussel stations were investigated in 2005, of which fourteen also in 2004. These fourteen were investigated prior to 2004-2005 in 1990-1993. The longest times series, from 1997 to 2006, is with blue mussel from the Husvågen area in Lofoten (st. 98A2). Blue mussel have been collected from two sites in the Lofoten area. In 1992-1993 samples were collected from Litj Skarvsundet (98A1) in the Skrova area of Lofoten, however, during the period 1994-1996 blue mussel were not found here, but nearby in the Skrova harbour (98X). In 1997 st.98A2 was established at Husvågen, roughly 18 km north of Skrova, in a small fjord remote from any apparent point source of contamination, and hence considered comparable. However, the statistical trend-analyse is based only on the Husvågen data.

In 2006, the blue mussel were only insignificantly contaminated (SFT's Class I), which has been generally the case since 1997 (Appendix I and Appendix J). Plaice from Husholmen (98F2) in the Lofoten area had overconcentrations of cadmium, 3 times “background”.

1.3.7. Exposed area of Varangerfjord near the Russian border

The remaining and northern area of JAMP in Norway stretches north of 68°N and east from a longitude of 17 to 29°E (Appendix G). Twelve mussel stations were investigated in 2006, ten of which were also investigated during the period 1994-1995. Only two mussel stations, one cod station and one plaice station were investigated in the Varangerfjord (at approximately 70°N).

In 2006, the mussels were only insignificantly contaminated (Class I) except for the moderate concentrations (Class II) found at six stations remote from point sources (stations 41A, 43A, 46A, 47A and 49A). This could indicate a natural regional difference (Appendix I and Appendix J).

Sediment was sampled at 10 stations in remote from point sources from Vågsfjorden (st.41S, near Harstad) to Varangerfjorden (10S). All were investigated previously in 1994. Surficial sediment was moderately polluted with TBT at all stations, nickel at all but Syltefjord (st.49S), and chromium at all but Tanafjord (st.48S) and Syltefjorden; benzo[*a*]pyrene at Tanafjord and Syltefjord (Appendix K).

1.3.8. Norwegian Pollution and Reference Indices (The Index Programme)

The Norwegian Pollution Control Authority (SFT) has requested a specific and small group of indices to assess the quality of the environment with respect to contaminants - The Index Programme. One index is based on the levels and trends of contaminant concentrations in blue mussel collected annually from a selection of the more contaminated fjords in Norway (Appendix L). SFT has also requested the testing of this index against “reference” stations from selected areas and fjords.

The Index scale varies from 1 to 5. Index 1 means that all areas or fjords are insignificantly polluted (Class I in SFT's environmental quality classification system (Molvær *et al.* 1997)), Index 5 means that at least one sample from each area or fjord is extremely polluted or Class V in SFT's system.

Nine fjord areas were used to calculate the Pollution Index. Taking the supplementary stations (Strømtangen, Flåøya, Moholmen and Toraneskaien) and analyses of TBT and dioxins into consideration, the Index was 2.9 for 2006 compared to 3.1 for 2005 (cf. Appendix L). A value between 3 and 4 would be between “Marked” and “Severe” Classes in the SFT system. A value bewteen 2 and 3 would be between the “Moderate” and “Marked” Classes. Indices calculated with and without supplementary stations and analyses have been presented earlier (cf. Green *et al.* 2004a, b).

Five areas were included in the Reference Index for 2006 compared to the same five for 1998-2005, and seven or eight fjords used in previous years. With the new calculation where supplementary analyses of TBT are included, the Reference Index was 1.4 for 2006, unchanged from 2005. Comparison between the old and new calculations has been done for 2002 and 2003 (cf. Green *et al.* 2004a, b). A value between 1 and 2 would be between “Slight” and “Moderate” Classes. Four of the five fjords/areas included TBT analyses.

The use of the indices to assess the general level of pollution in contaminated or reference areas of coastal water for the period 1995 to 1999 has been reviewed (Green & Knutzen, 2001). The conclusions were mainly that the sample and analytical strategies lacked adequate coverage of the relevant contaminants and geographical areas. Furthermore, the report suggested supplementing the assessment of this type with relevant analyses of sediment. In 2002 the programme was improved by including more stations and parameters relevant to the blue mussel Pollution Index.

It is not the intent of the application of the indices to give a station by station account. However, time trend analyses for the entire period (1995-2006) have been calculated and show both significant upward and downward trends in blue mussel (cf. Appendix I). Some cases are worth noting (2006 median Class / trend):

- Inner Oslofjord, Gressholmen (st.30A, Map 1, Appendix G) – TBT, ΣPCB-7, Class II / *downward*,
- Inner Oslofjord, Gressholmen (st.30A, Map 1, Appendix G) – benzo[*a*]pyrene, Class II / *upward*,
- Frierfjord area, Bjørkøya (Risøyodden) (st.71A, Map 3, Appendix G) - HCB, Class III / *downward*,
- Frierfjord area, Gjemesholmen (st.I712) and Strømtangen (st.I713) (Map 3, Appendix G) - TBT, Class II / *downward*,
- Sørfjord, Eitrheimsneset (st.52A, Map 6, Appendix G) – Cd, Class II / *downward*,
- Byfjorden (Bergen), Nordnes (st.I241) in Bergen harbour (Map 7, Appendix G) – HCB, Class III / *upward*,
- Byfjorden (Bergen), Gravdalsneset (st.I242) in Bergen harbour (Map 7, Appendix G) – HCB, Class II / *downward*.

1.4. Biological effects methods for cod

The rationale to use biological effects methods within monitoring programmes is to evaluate whether marine organisms are affected by contaminant inputs. Such knowledge can not be derived from tissue levels of contaminants only. In addition to enable conclusions on the health of marine organisms, some biomarkers assist in the interpretation of contaminant exposure and bioaccumulation. The biological effects component of the Norwegian JAMP is possibly the most extensive of its type in Europe and includes imposex in gastropods as well as biomarkers in fish. The four chosen methods for fish were selected for specificity, for robustness and because they are among a limited set of methods proposed by international organisations, including OSPAR and ICES.

The JAMP-programme for 2006 included five biological effects methods (BEM): OH-pyrene, ALA-D, EROD-activity, CYP1A and TBT (Table 2). The first four are discussed in this chapter (Figure 12 to Figure 14) and TBT is discussed separately (cf., section 1.5). Results for OH-pyrene, ALA-D, EROD and metallothionein (MT) in cod and flatfish, 1997-2001, have been reported earlier (Ruus *et al.* 2003). For the 2006 investigations OH-pyrene, ALA-D, EROD-activity and CYP1A were measured in Atlantic cod from the inner Oslofjord (30B), Sørfjord (st.53B), and Sotra-Bømlo area (23B). OH-pyrene was also measured in cod outside Lista (15B). It has become clear that cod caught in the open coastal area outside Lista are more strongly affected by PAHs than cod at the other stations, despite the large water exchange in that area (Ruus *et al.* 2003). Furthermore, stations from the inner Oslofjord and Sørfjord are considered to be more contaminated with metals and organochlorines than the other stations.

Table 2. Summary of biological methods employed by the JAMP-2006.

Code	Name	tissue sampled	Specificity
OH-pyrene	Pyrene metabolite	fish bile	PAH
ALA-D	δ-aminolevulinic acid dehydrase inhibition	fish red blood cells	Pb
EROD-activity	Cytochrome P4501A-activity (CYP1A/P4501A1, EROD)	fish liver	planar PCB/PCNs, PAHs, dioxins
CYP1A	Relative amount of cytochrome P450 1A-protein	fish liver	Supporting parameter for EROD-activity
TBT	Imposex/Intersex	snail soft tissue	organotin

Under controlled conditions the measures derived from OH-pyrene, EROD-activity and CYP1A increase with increased exposure to their respective inducing contaminants. The activity of ALA-D on the other hand is inhibited by contamination (i.e., lead), thus lower activity means higher exposure.

As in most previous years, 25 individual cod were sampled for biological effects measurements at each station. However, since 2002 only three stations (four for OH-pyrene) were sampled, instead of eight stations as in previous years. Furthermore, no samples for BEM were taken from flatfish. All fish were collected by local fishermen and kept alive until sampling by NIVA staff within 5 days. There is a continuous process to train and inform the fishermen that collect fish for JAMP to ensure the quality of the material.

1.4.1. OH-pyrene metabolites in bile

Detection methods for OH-pyrene have been changed (improved) two times since the initiation of these analyses in the JAMP programme. In 1998 the support/normalisation parameter biliverdin was changed to measurement of light absorbance at 380 nm. Furthermore, in 2000, the use of single-wavelength fluorescence for quantification of OH-pyrene was discontinued and the use of HPLC separation with fluorescence detection was implemented. All data shown in Figure 12 were obtained by the latter method. Although there is a good correlation between results from the two methods they can not be compared directly. The single wavelength fluorescence method is naturally more unspecific and will include fluorescence from more components than the HPLC method, which has extremely high specificity towards individual metabolites. The interpretation of OH-pyrene data is therefore primarily focused on the differences between the stations within each year.

As in 2005, the median concentrations of OH-pyrene metabolites in bile from cod ranged between stations in the following order in 2006: Oslofjord (st. 30B) > Sørfjord (st. 53B) > Sotra-Bømlo area (reference; st. 23 B) > Lista (st. 25B). However, variability was high, and the highest at Lista (st. 15) as previous years. More specifically, in 2006 the median concentration of OH-pyrene metabolites in cod from the inner Oslofjord (st.30B), was a factor >6 higher than that of cod from Lista (st.15B). (Figure 12, Appendix I). This result differ from previous years (before 2000, and in 2001).

For 1998, 1999, 2001 the median concentrations of OH-pyrene in cod from Lista (st.15B) were higher than at stations 30B, 53B and 23B (no samples from st.15B in 2000). In 2002, the OH-pyrene levels at Lista were above those at the reference locality, Karihavet (23B), but lower than in the inner Oslofjord (st.30B) and in the inner Sørfjord (st.53B). In 2003 and 2004 concentrations were below those from the inner Oslofjord (st. 30B) but above the reference (st.23B) and those found in the inner Sørfjord (st.53B). It is worth mentioning again that the variability in the OH-pyrene bile concentrations in cod from Lista (st.15B) are relatively large (compared to at the other stations), all years (Figure 12). A significant *downward* trend in OH-pyrene in bile from cod at Lista is visible for the period 1998-2006 Figure 12, Appendix I). Lista is located in an area with a large discharge of PAH to water from an aluminium-smelter. The fish were collected on the open coast and the discharge from the smelter occurred in a small bay about 2-3 km away.

In 2006, as in most years, concentrations of OH-pyrene in cod from Sørfjorden (53B) were higher than the concentrations in cod from Sotra Bømlo (23B) This also confirm the generally assumed contamination of this area.

Bile metabolites of PAH can be detected within a short period (hours) following exposure, and holding conditions prior to sampling may affect results. However, measures were taken in 1998 and 1999 to minimise or remove the problem. Given the precautions taken, it is unlikely that the observed levels have been caused by storage of fish prior to tissue sampling.

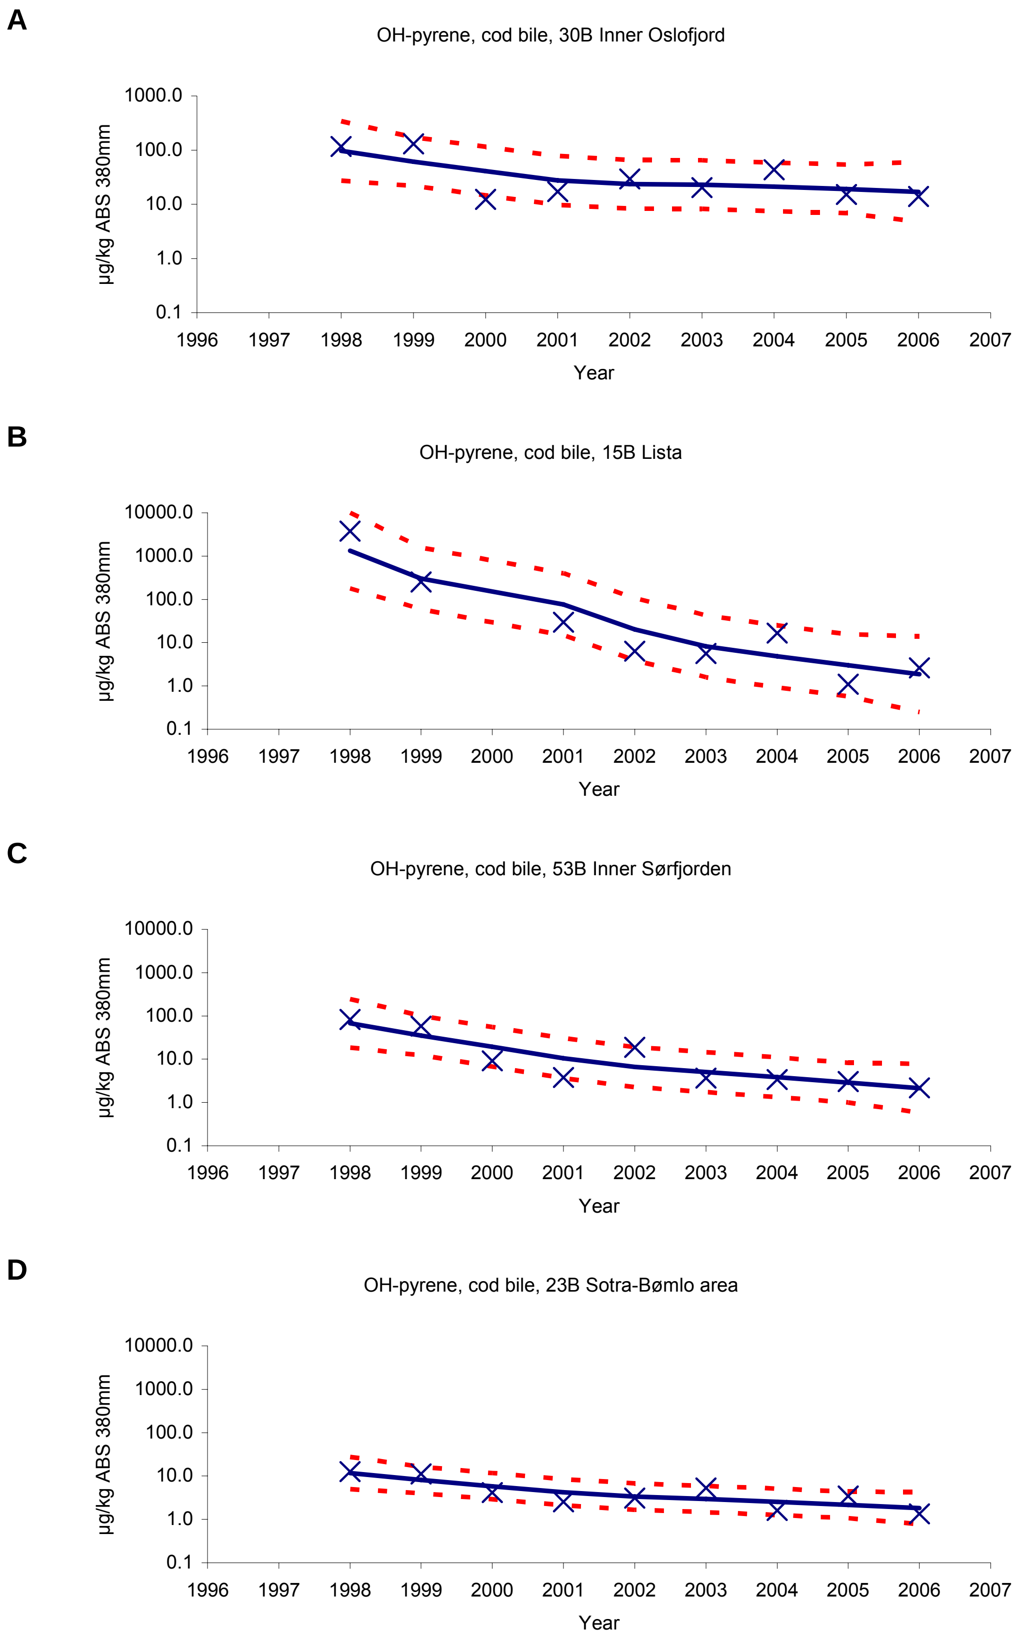

Figure 12. Concentration of OH-pyrene (µg/kg ABS 380nm) in bile from Atlantic cod collected at the inner Olsofjord (st.30B), Lista (st.15B), inner Sørfjorden (st.53B) and Sotra-Bømlo (st.23B). (cf. Appendix G and Appendix I, and key in Figure 21). **NB: log-scale.**

1.4.2. ALA-D in blood cells

Inhibited activity of ALA-D indicates the influence of lead contamination. Although ALA-D inhibition is lead-specific, it is not possible to rule out interference by other metals or organic contaminants. Previous studies indicate that only zinc may ameliorate the effect of lead to some extent, but the effect is variable and weak. Other studies have also shown ALA-D to be a remarkably robust biomarker and factors such as sex, age or season do not appear to affect the response.

Most years the activity of ALA-D in cod was generally inhibited in the inner Oslofjord (st.30B) and inner Sørfjord (st.53B), compared to reference stations, i.e. outer Oslofjord (st.36B), Karihavet in the Sotra-Bømlo area (st.23B), and Varangerfjord (st.10B). This was the case for 1997, 1998, and 2000-2006 (Figure 13 and Appendix I,). For all years 1997-2006 the median activity of the enzyme in cod from inner Sørfjord (st.53B) was generally lower than on the open coast (Karihavet - st. 23B), about 130 km to the west.

Since 2002, ALA-D has been measured only in cod from Karihavet (st. 23B), inner Oslofjord (st.30B) and inner Sørfjord (st.53B). In 2006 as in previous years, the inibition was largest in the inner Sørfjord and the inner Oslofjord, although the trend was less evident than in 2005 (Figure 13, Appendix I). This indicates pollution of lead (and possibly other metals) in these two fjords. An increase in median ALA-D activity could be seen over the years from 2002 to 2006 indicating less exposure. In the Oslofjord (st. 30B), this is consistent with a decrease in hepatic lead concentrations since 2002 (Appendix I). .

No significant temporal trends in ALA-D activity were found neither in Sotra-Bømlo (23B), Oslofjord (st.30B) or Sørfjord(st.53B).

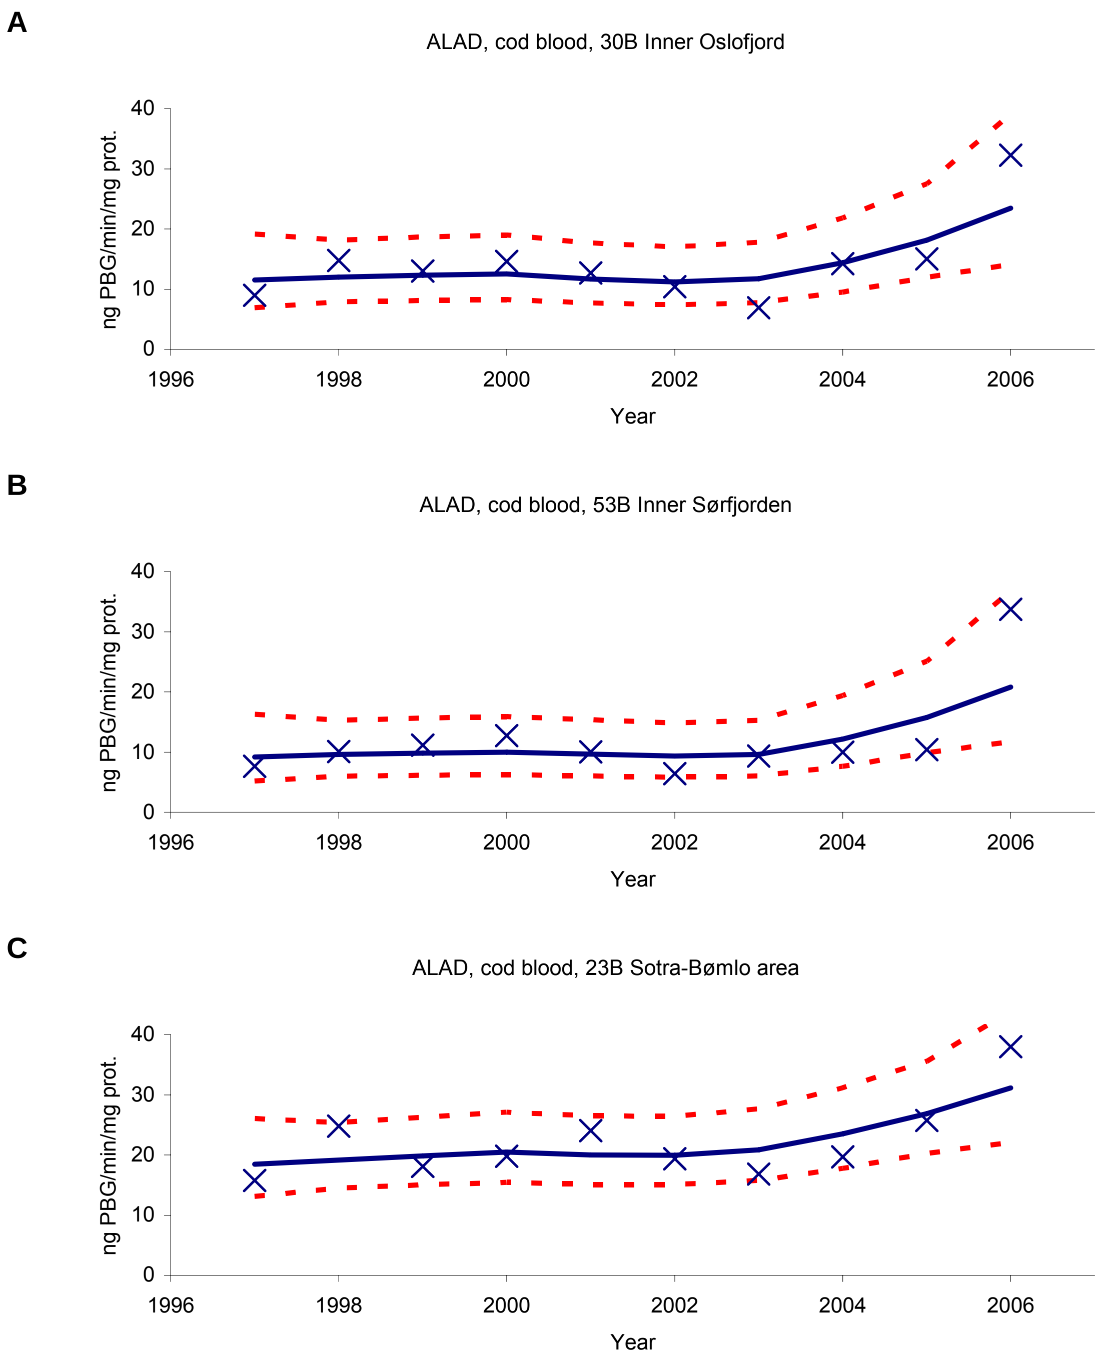

Figure 13. Activity of δ-aminolevulinic acid dehydrase (ALA-D, ng PBG/min/mg protein) in red blood cells from Atlantic cod collected at the inner Olsofjord (st.30B), inner Sørfjorden (st.53B) and Sotra-Bømlo (st.23B). (cf. Appendix G and Appendix I, and key in Figure 21). OBS: lower activity means higher exposure and vice versa.

1.4.3. EROD-activity and amount of CYP1A protein in liver

EROD-activity

High activity of hepatic cytochrome P4501A activity (EROD-activity) normally occurs as a response to the contaminants indicated in Table 2. It was expected that higher activity would be found at the stations that were presumed to be most impacted by planar PCBs, PCNs, PAHs or dioxins, i.e. inner Oslofjord (st.30B) and inner Sørfjord (st.53B/F). In 2005, no such differences were evident. In 2006 median EROD-activity was highest in the Oslofjord (st. 30B), allthough variability was high, There were no differences between the cod from the inner Sørfjord and Karihavet in 2005 (Figure 14, Appendix I). Previous years have also shown that EROD-activity in both fish from the inner Oslofjord and from the inner Sørfjord are not consistently higher than at the reference station on the west coast (st.23B). No significant temporal trends were found at these three stations.

No adjustment for water temperature has been made. Fish are sampled at the same time of year (September-November) when differences between the sexes should be at a minimum. Statistical analyses indicate no clear difference in activity between the sexes (Ruus *et al.* 2003). It has been shown that generally higher activity occurs at more contaminated stations (Ruus *et al.* 2003). However, the response is inconsistent (cf. Appendix I), perhaps due to sampling of populations with variable exposure history. Besides, there is evidence from other fish species that continuous exposure to e.g. PCBs may cause adaptation, i.e. decreased EROD-activity response.

In 2006, there was a significant correlation between the EROD-activity and the amount of CYP1A protein measured, corresponding to earlier results (Green *et al.* 2004b). The goodness of fit for the linear model was, however, poor (R^2=0.32). Furthermore, more evidently than the EROD-activity, CYP1A was in 2006 consistently higher in the inner Oslofjord (st.30B) than in the inner Sørfjord (st.53B) and at the reference station on the west coast (st.23B) (Figure 15, Appendix I).

(cf. Appendix G and Appendix I, and key in Figure 21). **Note: for some years the upper confidence interval line is off-scale in Figure A.**

1.4.4. Concluding remarks

The application of BEM methods within JAMP through the years 1997-2001 (and 2004) indicated that the location Lista (st. 15B), which was previously regarded as only diffusely polluted, had an input of PAH which was sufficient to clearly affect fish in the area. However, in 2002 and 2003 the median concentrations of OH-pyrene in cod from Lista were lower than those from the inner Oslofjord (st.30B) and inner Sørfjord (st.53B) and in 2005, OH-pyrene concentrations in cod from Lista were the lowest ever recorded within JAMP. In 2006, the lowest median OH-pyrene concentration was found at Lista, as in 2005. As in some previous years, relatively large variability was observed between individuals from Lista.

Results for the period 1997-2005 indicated that there are lead effects, shown by decreased activity of the enzyme ALA-D in the two most strongly polluted areas, i.e. cod from the inner Oslofjord (st.30B) and cod from the inner Sørfjord (st.53B). This indication was less evident in 2006.

The highest median EROD-activity was found in the inner Oslofjord (st.30B). Median EROD-activity in the inner Sørfjord was no higher than in the less contaminated Sotra-Bømlo area. Previous years have also shown that EROD-activity in fish from the inner Oslofjord and Sørfjord stations are not consistently higher than at other, presumed cleaner stations. The amount of CYP1A protein was higher in the Osloford (st.30B) than in the Sørfjord (st.53B), and the Sotra-Bømlo area (st.23B).

1.5. Effects and concentrations of organotin

Effects from organotin in dogwhelk (*Nucella lapillus*) were investigated at 8 JAMP and Index stations in 2005. Concentrations of organotin in dogwhelk and blue mussel (*Mytilus edulis*) were quantified at 8 and 12 stations, respectively, and including both the JAMP and Index stations. The stations are located along the coast of Norway and samples were collected August-November 2005 (Appendix E and maps in Appendix G).

TBT-induced development of male sex-characters in females, known as imposex (Vas Deferens Sequence Index - VDSI), was analysed according to OSPAR-JAMP guidelines. Detailed information about the chemical analyses of the animals is given in Følsvik *et al*. (1999).

1.5.1. Dogwhelk

The effects from organotin were generally low. Espevær (st. 22G) on the West coast had a VDSI of 4, (Appendix J). The remaining 7 stations had low VDSI (<2). No effects were found at Brashavn (st. 11G). A significant *downward* trend was found at Færder (st. 36G) (Appendix I, Figure 16).

Concentrations of organotin from the eight stations measured were relatively low (<0.24 mg/kg d.w.). As in 2003 and 2004 the highest organotin levels were found at Haugesund (st. 227G2, Appendix I, Appendix J, Figure 17). Concentrations had decreased compared to 2003 and 2004, however, no statistically significant temporal trends for the period 1997-2005 were found.

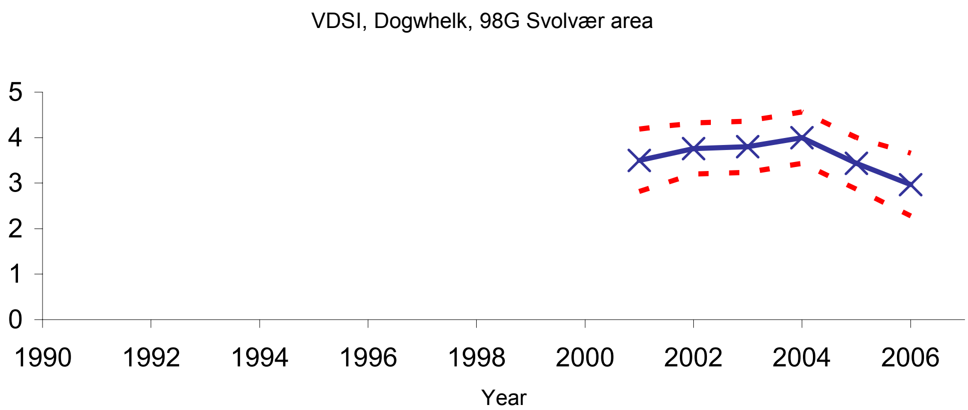

Figure 16. Imposex (VDSI) in dogwhelk (*Nucella lapillus*) at 2 stations in southern Norway; Færder (36G) and Melandholmen-Flatskjær of the Haugesund area(227G1 and 227G2) and one at Lofoten (98G). Data from 1991 (Harding *et al*. 1992) and 1993 (Walday *et al*. 1997). (cf. Appendix G and Appendix I, and key in Figure 21).

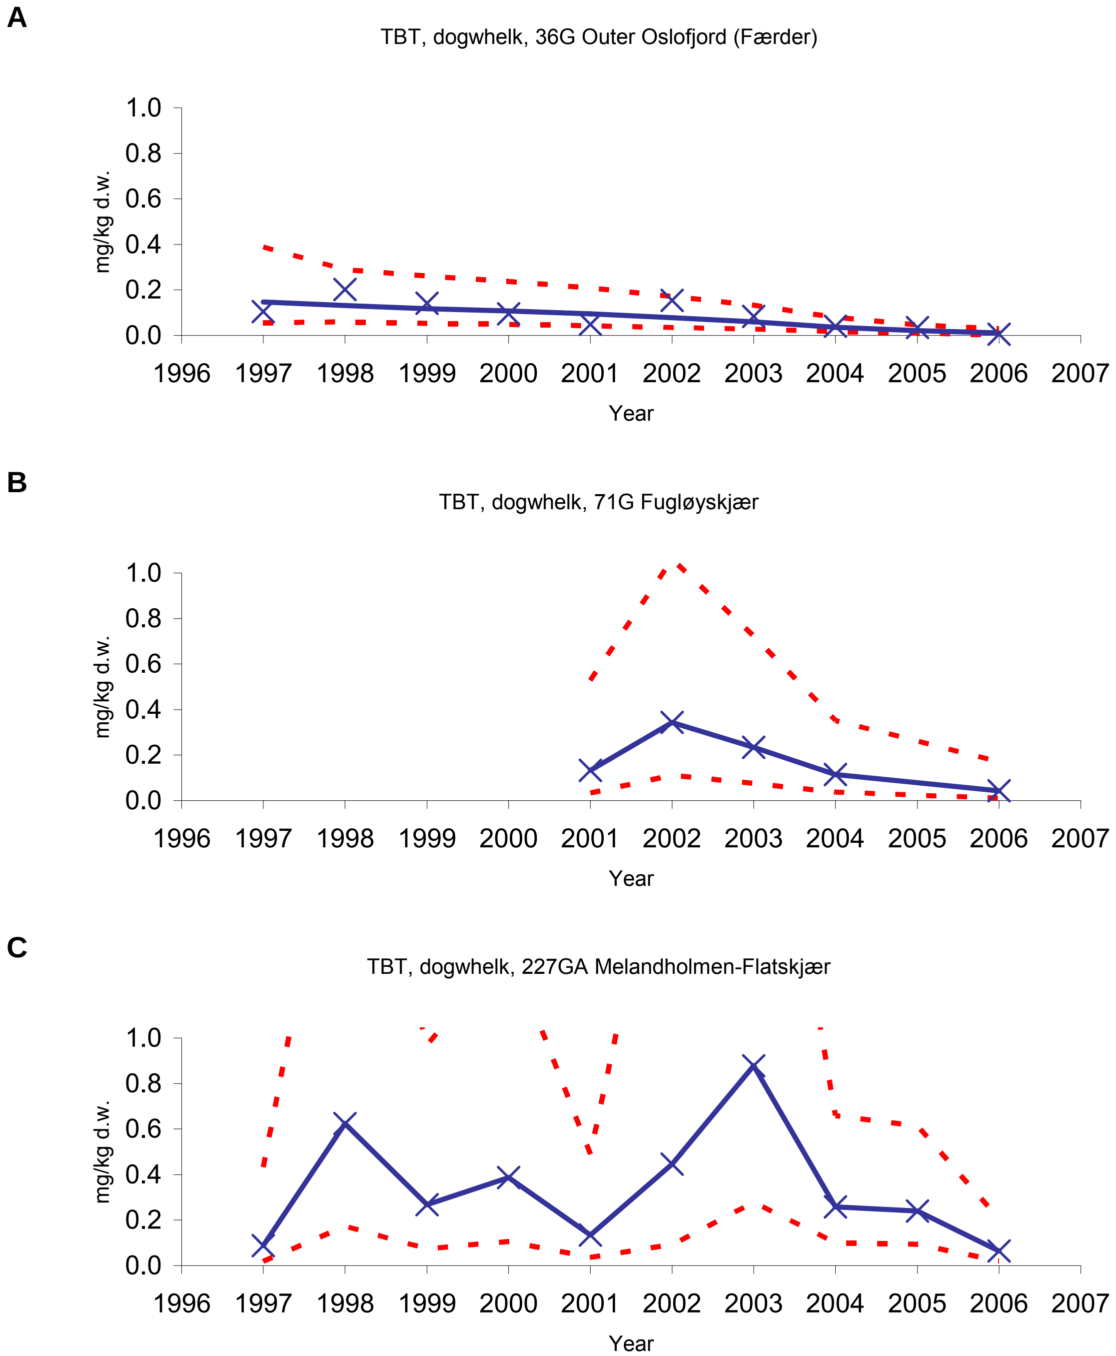

Figure 17. Median concentration of TBT (on a formulation basis) in dogwhelks (*Nucella lapillus*) from outer Oslofjord (36G), Langesundsfjord (west of Oslofjord) (st.71G) and Melandholmen-Flatskjær of the Haugesund area (227G1 and 227G2), mg/kg (mg TBT/kg) dry weight. NB: (cf. Appendix G and Appendix I, and key in Figure 21). Note: for some years the upper confidence interval line is off-scale in Figures B and C.

1.5.2. Blue mussel

Blue mussel was severely contaminated with organotin at one station in the inner Oslofjord (Index st. 301); Class IV in SFTs environmental classification system (Appendix J, Figure 18). Moderately (Class II) or markedly (Class III) polluted blue mussel were not only found in other harbour areas (e.g. the Frierfjord (st.712, and 713) and Haugesund (st.227A)) but also in an area in Espevær (st. 22A) on the West coast presumably remote from point sources. Low median concentrations (Class I) were found at the northern stations (st.11X) and at Farsund (st.15A) as well as some stations in western Norway. Significant *downward* trends were found in the inner Oslofjord (st.30A) and the Langesund area (st. 71A).

1.5.3. Concluding remarks

The presence of organotin (as TBT) in Norwegian waters exceeded acceptable levels at 7 of the 13 blue mussel stations monitored in 2006, not only in harbour areas but also one station presumably remote from known point sources. Concentrations of organotin in blue mussel and dogwhelk were elevated, and biological effects from TBT were found in dogwhelk from all but one of the fourteen stations investigated. eight of the twelve timeseries for TBT in blue mussel showed significant *downward* trends. This may be an indication that the ban on the use of TBT in antifouling on boats <25 m of length, in effect since 1.January 2003, has had an effect.

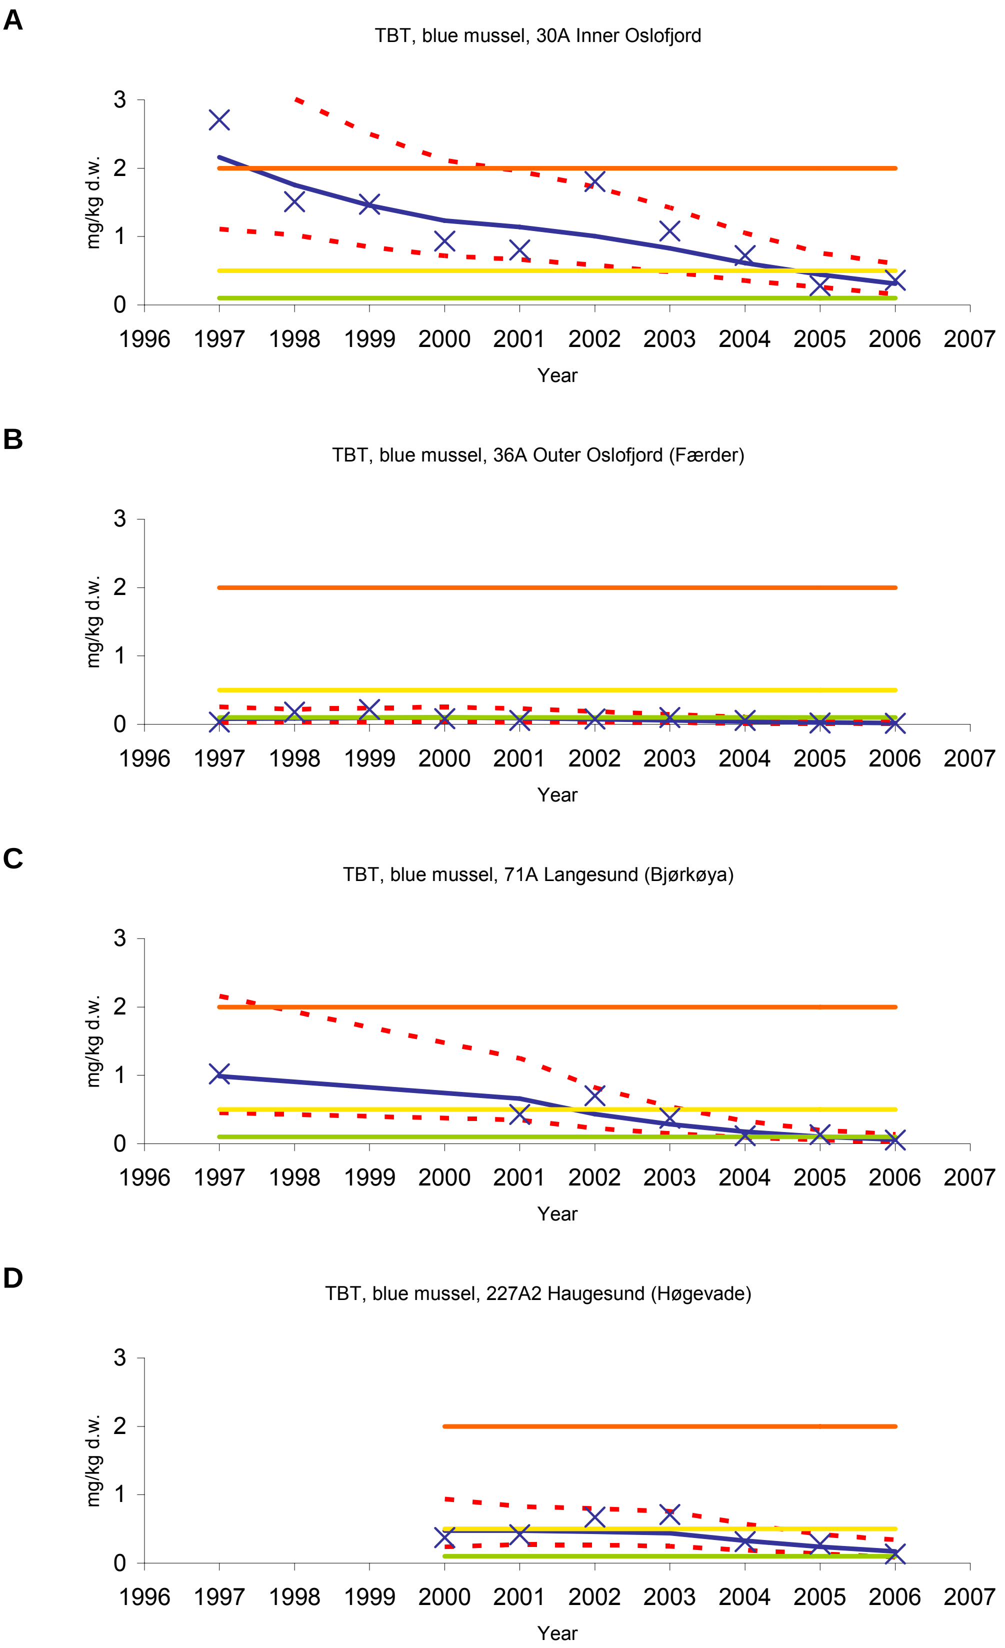

Figure 18. Median concentration of TBT (on a formulation basis) in blue mussel (*Mytilus edulis*) from inner (st.30A) and outer (st.36A) Oslofjord, Langesundsfjord (west of Oslofjord) (st.71A) and Haugesund (St.227X), mg/kg (mg TBT/kg) dry weight. (cf. Appendix G and Appendix I, and key in Figure 21). Note: for 1997 in Figure A the upper confidence interval line is off-scale. Note: horizontal line for Class I is near x-axis

1.6. Polybrominated diphenyl ethers

For the second year, polybrominated diphenyl ethers (PBDs) were investigated. Three cod stations were selected: inner Oslofjord (st.30B), inner Sørfjord (st.53B) and Karihavet (st.23B) (Figure 19). The median concentration of sum BDE was highest in the inner Oslofjord and lowest at the reference area in Karihavet. Median concentrations found at presumed reference stations of Svolvær, Færder, Utsira and Bømlo-Sotra indicated that a high background in these diffusely contaminated areas might be 30 µg/kg w.w. (Fjeld *et al.* 2005) which was higher than the median found in inner Sørfjord and Karihavet. The median found in the inner Osloford was 60 µg/kg w.w. and in the interval of 37-112 µg/kg w.w. found in other contaminated areas (Fjeld *et al.* 2005; Berge *et al.* 2006).

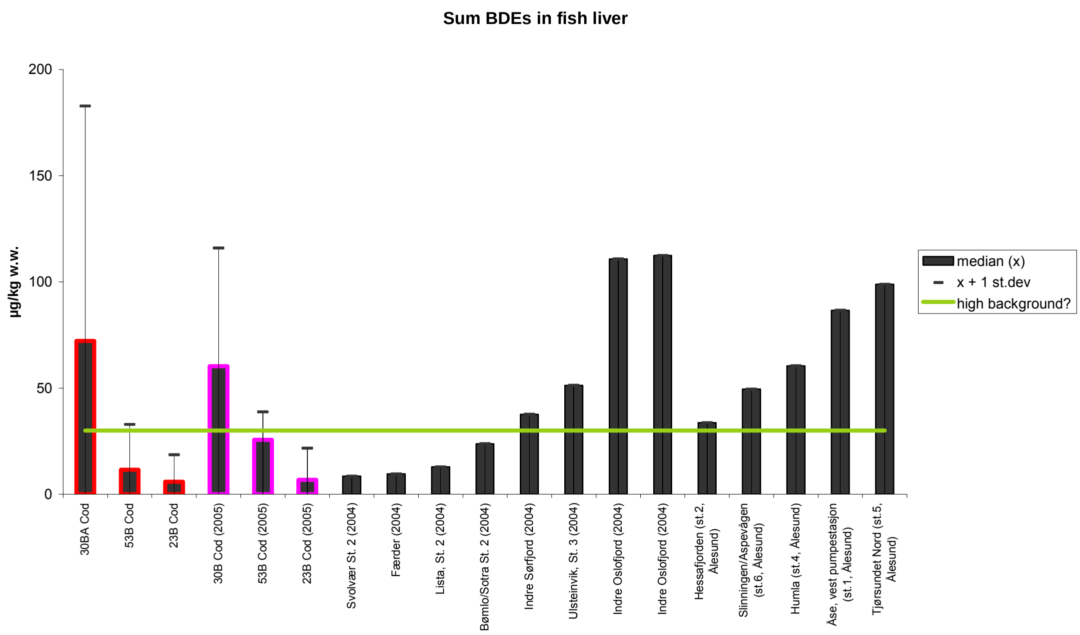

Figure 19. Polybrominated diphenyl ethers (PBDE) in liver of cod (*Gadus morhua*) at 3 JAMP-stations in southern Norway (inner Oslofjord - 30B, inner Søfjord - 53B, and Karihavet - 23B) bar shown with red (2006) and purple (2005) borders, and results from two other investigations (Fjeld *et al.* 2005 – marked as 2004, Berge *et al.* 2006), see text.

1.7. PFOS

For the first time under JAMP, perfluroalkyl compounds (PFAS) were investigated. Three cod stations were selected: inner Oslofjord (st.30B), inner Sørfjord (st.53B) and Karihavet (st.23B) and monitored in 2005 and 2006 (Figure 19). The median concentration of the indicator PFAS compound perfluoroktylsulfonate (PFOS) was highest in the inner Oslofjord. Median concentrations found at presumed reference stations of Svolvær, Frakfjord, Varangerfjord indicated that a high background in these diffusely contaminated areas might be 30 µg/kg w.w. (Bakke *et al.* 2007a) which was higher than the median found in inner Sørfjord and Karihavet. The median found in the inner Osloford was 60 µg/kg w.w. and in the interval of 37-112 µg/kg w.w. found in other contaminated areas (Fjeld *et al.* 2005), Berge *et al.* 2006).

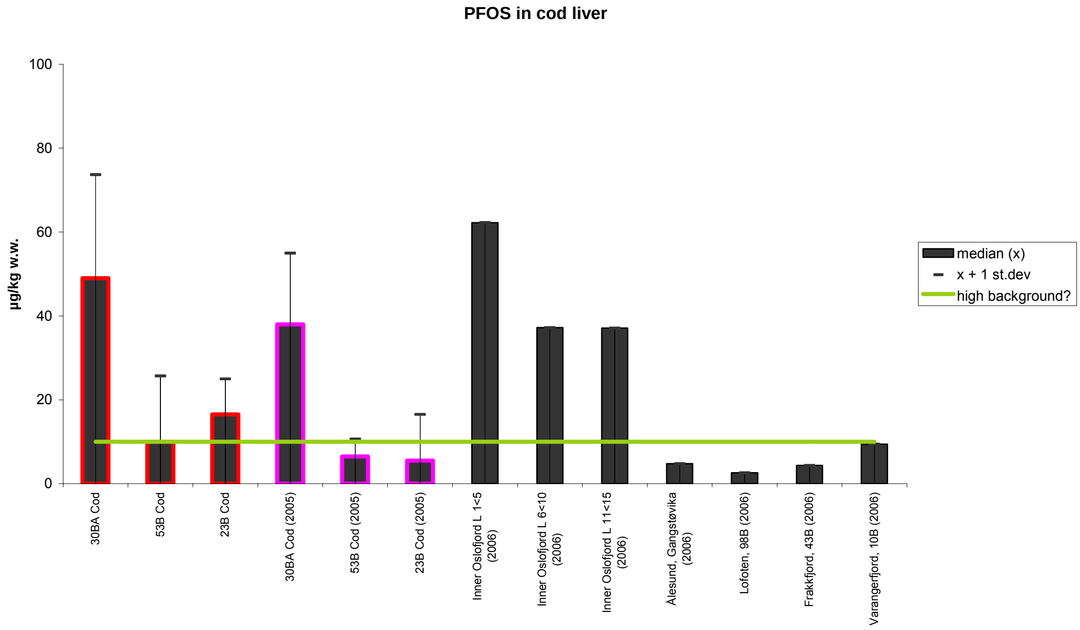

Figure 20. Perfluoroktylsulfonate (PFOS) in liver of cod (*Gadus morhua*) at 3 JAMP-stations in southern Norway (inner Oslofjord - 30B, inner Søfjord - 53B, and Karihavet - 23B) bar shown with red (2006) and purple (2005) borders , and results from one other investigation (Bakke *et al.* 2007a – marked as 2006), see tex

1.8. Comment on dioxins

Recent assessment of dioxin data from the regional Grenland monitoring in cod liver (Bakke *et al.* 2007b) has indicated that an apparent downward trend in wet-weight concentrations over the last 16 years in the most polluted fjord area may be a spurious effect of a major long-term reduction in fat content; the concentrations on fat basis are constant over the years, apart from a few deviations in some years. The decrease in fat content may be due e.g. to (unknown) changes in general life conditions in the fjord. Cod liver samples from the other fjord areas do not show a similar long-term decrease in fat content, and therre is not a clear connection between lipid content and wet weight based dioxin levels for these fjords. This emphasizes the need to investigate the relations between contaminant levels and biological characteristics to interpret observed time series of contaminant levels in biota as signs of changes in the external environment.

1.9. Overall conclusions

In regards to *temporal trend* assessment, 807 timeseries were analysed (Appendix I). There were 137 significant trends detected, of which 116 were downward and 21 upward.The following cases should be noted:

- ΣPCB-7 in blue mussel from the inner Oslofjord has *decreased* since 1988;
- Mercury in cod fillet from the inner Oslofjord has *increased* since 1984;
- Cadmium in blue mussel from the inner Oslofjord (1 st.) has *increased* since 1984;
- HCB in mussel from Langesundsfjorden has *decreased* since 1983;
- Cadmium in blue mussel in the Hardangerfjord/Sørfjorden (3 st.) has *decreased* since 1987;
- Mercury in flounder fillet from the inner Sørfjorden has *increased* since 1988;
- ΣPCB-7 and ppDDE in flounder fillet from the inner Sørfjorden has *decreased* since 1990;
- Lead in blue mussel in the Hardangerfjorden (2 st.) has *decreased* since 1990;
- TBT has *decreased* in blue mussel at 7 of the 12 stations monitored (Gressholmen - st.30A, Bjørkøy in the Langesund area – st.71A, Strømtangen at the mouth of the Frierfjord – st.I713, Risøy – st.76A, Ullerø area – st.15A, Husvågen, Lofoten – st.98A2, Varangerfjord area– st. 11X);
- ΣPCB-7 in blue mussel from Gjemesholmen also in the Langesund area has *decreased* since 1995
- ΣPAH has *decreased* in blue mussel from Odderø in the Kristiansand harbour (st. I133) since 1995.

Study of the power of temporal trend monitoring was useful in assessing existing sampling strategies, however, modifications might be needed to account for local conditions (see Appendix O in Green *et al.* 2000).

The 2006 investigation also includes results on Norwegian Pollution Control Authority Pollution Indices (Appendix L), and discussion of the results of biological effects methods including imposex and intersex (chapters 1.4 and 1.5).The pollution index dropped from “Marked”-“Severe” to “Moderate”-“Marked”. The Reference index remained unchanged from 2005. The results from the biological effects methods indicate the effects of contamination. The a large number of significant downward trends were found in TBT indicate that regulatory action has lead to improvement in the investigated areas.

In regards to *spatial distribution* assessment, the concentrations found in 2006 are indicated in the bar graphs shown in Appendix J. Provisional “high background" levels were used to identify elevated concentrations. This assessment revealed no new areas of concern that are not currently under surveillance.

In regards to *effects of hazardous substances*, 40 timeseries were analysed (Appendix I). There were 7 significant trends detected, all of which were downward. Levels found in 2006 are indicated in the bar graphs shown in Appendix J. No criteria for classification have been proposed.

In regards to *risk to human health*, attention should be called to the list from Norwegian Food Safety Authority (*Mattilsynet*) which names the restrictions and recommendations concerning the sale and consumption in Norway for seafood taken from 32 Norwegian fjord areas (Table 3). Furthermore, *Mattilsynet* has issued general advice to avoid consumption of seafood taken in or in close proximity to harbours (see www.miljostatus.no > *vannforurensning* > *miljøgifter, vann* > *miljøgifter, marint* > *kostholdsråd* and review by Økland 2005).

Table 3. Summary of action taken by the Norwegian Food Safety Authority (*Mattilsynet*) concerning the consumption and sale of fish products along the Norwegian Coast (see www.miljostatus.no > *vannforurensning > miljøgifter, vann > miljøgifter, marint > kostholdsråd* and review by Økland 2005). Restrictions on sale vary and may concern the whole or part of fish product.

Area of concern (km^2)	Main parameters of concern	Last year of issue/ adjustment	Main fish/shellfish product of concerned	Recommendations or restrictions of concern:
Mid [1] and Inner Oslofjord (498.9) (includes Drammensfj.)	PCB	2002	fish liver, eel	Consumption and sale

Honningsvåg (3.3)	PAH	2002	mussels	Consumption and sale

1) Includes, Hvitsten, Moss, Horten og Holmenstrand
2) Organochlorine compounds
3) Concerns only Eidsbotn
4) A brominated flame retardant
5) Grounds for concern were cleared in 2005
6) Exclusive Vedavågen

Until 2004 JAMP issues posed questions to which monitoring should provide answers, but since 2004 JAMP has been geared towards OSPAR strategy themes with specific products to be addressed (cf SIME 2004a). The relevant products and related parts of Norwegian JAMP relevant to some of these products are shown in Table 4. viz (from SIME 2004b):

Table 4. Component of the CEMP, JAMP products and related Norwegian JAMP work (cf., OSPAR 2007, SIME 2004b).

[1]) Certain Brominated Flame Retardents
[2]) Perfluoroktylsulfonate
[3]) Polychlorinated dibenzodioxins and furans
[4]) PAH- and Metal-Specific Biological Effects
[5]) General Biological Effects
[6]) From SIME 2004b:

AA-2 An assessment in 2010 of the quality status of the OSPAR maritime area and of its sub-regions.

HA-4 A more elaborated assessment by 2009 of biological effects of hazardous substances in the maritime area;

HA-5 An assessment by 2009 of temporal trends and (where relevant/feasible) spatial distribution for the hazardous substances where periodic sampling and analysis is undertaken, in particular under CAMP, CEMP and RID;

HA-6 A general assessment by 2009 of the development in the quality status of the maritime area in relation to hazardous substances that should take into account the results of the assessments under HA-1 and HA-5, HA-2 and HA-4 and HA-3, and the results of any screening of levels of substances in the marine environment covered by HM-3;

HM-3 When appropriate, identification of the likely impacts on the marine environment of substances recorded, inter alia, in source inventories, or identified by screening methods.

2. Technical Details

2.1. Compliance with guidelines/procedures

2.1.1. JAMP programme

Samples were collected and analysed, where practical, according to OSPAR guidelines (OSPAR 1990, 1997, see also www.ospar.org/eng/ > *measures* > *list of other agreements*) and screened and submitted to ICES by agreed procedures (ICES 1996). The most important point of concern are those stations where insufficient number of fish were collected (cf. Appendix H).

2.1.2. Overconcentrations and classification of environmental quality

Classification used in this report is primarily based on the Norwegian Pollution Control Authority environmental classification system (Molvær *et al.* 1997). Focus is on the principle cases where *median* concentrations exceeded the upper limit to Class I in the Norwegian Pollution Control Authority's (SFT's) environmental quality classification system (cf. Molvær *et al.* 1997). The relevant extract from the system is shown in Table 5 and Table 6, and show five classes from Class I, “insignificantly polluted”, to Class V, “extremely polluted”. However, the system does not cover all the contaminants in indicator species-tissues used in JAMP. To assess concentrations not included in the system provisional "high background" values were used (Table 7). The factor by which concentrations exceeded “high background” is termed **overconcentration**. It should be noted that there is in general a need for periodic review and supplement of this list of limits in the light of results from reference localities and introduction of new analytical methods, and/or units. Because of changes in the limits, assessments of overconcentrations for years prior to 1997 made in this report may not correspond to figures and assessments made in previous national comments. The median concentration can be found in the tables in Appendix I or figures in Appendix J.

A review by Knutzen and Green (2001b) of provisional "high background" concentrations based on recent JAMP-data generally confirmed that the reference concentrations (i.e., upper limit for Class I) in SFT's classification system, but recommended the following revisions (concentrations in µg/kg wet weight):

Cod liver - ΣDDT: Either increase limit from 200 to 300 or preferably replace ΣDDT with p,p-DDE and keep the limit at 200,
Cod liver - ΣHCH: Decrease limit from 50 to 30,
Cod liver - TEPCDD/PCDF: Decrease limit from 0.015 to 0.0,
Cod fillet - ΣPCB7: Decrease limit from 5 to 3,
Cod fillet - ΣHCH: Decrease limit from 0.5 to 0.3,
Blue mussel - ΣPCB7: Decrease limit from 4 to 3.

Furthermore, the review, supplemented by other studies (cf. Green & Knutzen 2003), also suggested the following decreases for Class I in fillet of flounder (µg/kg w.w.):

ΣPCB7: from 5 to 3,
ΣDDT: from 2 to 1 for p,p-DDE only.

The review did not recommend changes in the Class I limits for mercury in fish fillet (1 mg/kg w.w.) or mercury, cadmium, lead, zinc and copper in blue mussel (in the same order 0.2; 2; 3; 200 and 10 mg/kg d.w.). However, for chromium and nickel in blue mussel limits should be decreased from 3 to 2 and from 5 to 3 mg/kg d.w., respectively. Further, reference values for organochlorines were indicated for fillet and liver of fish species that are not included in the classification system (dab, plaice, lemon sole) and for lead and cadmium in liver of cod.

These recommendations for changes have been taken into account in this report. However, corresponding adjustment of Classes II-V has not been done, but should be considered once the above mentioned Class I revisions have been accepted by SFT. SFT is considering these recommendations in a current review of their classification system.

No attempt has been made to compensate for differences in size groups or number of individuals of blue mussel or fish. The exception was with mercury in fish fillet where six data sets in both cod and flatfish in this study showed significant differences between “small” and “large” fish (Appendix I). With respect to blue mussel, there is some evidence that concentrations do not vary significantly among the three size groups employed for this study (i.e. 2-3, 3-4 and 4-5 cm) (WGSAEM 1993).

With respect to Purpose A (health risk assessment), the Norwegian Food Safety Authority (SNT) is responsible for official commentary as to possible health risk due to consumption of seafood. Hence, the results of the JAMP pertaining to this purpose are presented only as a partial basis for evaluation.

1) Respectively: *Mytilus edulis, Gadus morhua, Platichthys flesus* and *Limanda limanda*.
2) From the Norwegian Pollution Control Authority Environmental Class I ("good") (Molvær *et al.* 1997).
3) Conversion assuming 20% dry weight.
4) Approximately 25% of ΣPCB-7 (Knutzen & Green 1995)
5) 1.5-2 times 75% quartile (cf. Annex B in Knutzen & Green 1995)
6) Assumed equal to limit for ΣDDT or ΣHCH, respectively, from the Norwegian Pollution Control Authority Environmental Class I ("good") (Molvær *et al.* 1997). Hence, limits for ppDDE and γHCH are probably too high (lacking sufficient and reliable reference values)
7) Mean plus 2 times standard deviation (cf. Annex B in Knutzen & Green 1995)
8) Estimated as sum of 7 individual PCB compounds (CB-28, -52, -101, -118, -138, -153 and -180) and assumed to be ca. 50% and 70% of total PCB for blue mussel and cod/flatfish, respectively.
9) With respect to revisions suggested by Knutzen & Green (2001b) and Green & Knutzen (2003), see text.

2.1.3. Comparison with previous data

A simple 3-model approach has been developed to study time trends for contaminants in biota based on *median* concentrations (ASMO 1994). A variation of this method was applied to mercury in fish fillet to distinguish trends in "small" and "large" individuals, the size of which may vary from year to year, station to station, depending on the catch. To determine the "small" fish, the sample is sorted by length and split into two groups of one or even numbers. The fish with median length in the smaller group is the "small" fish, and the median length in the larger group is the "large" fish. The concentration in these two size groups (one per group) determine the concentrations in the two groups. The method was first used on a large-scale basis by the Ad Hoc Working Group on Monitoring that met in Copenhagen 8-12. November 1993 (MON 1993). At this meeting it was agreed to apply the method on contaminants in fish muscle and liver on a wet weight basis and contaminants in soft tissue of blue mussel on a dry weight basis. The results for this assessment are presented earlier (cf. ASMO 1994). The method has been applied to Norwegian data and results are shown in Appendix H. The results can be presented as in Figure 21.

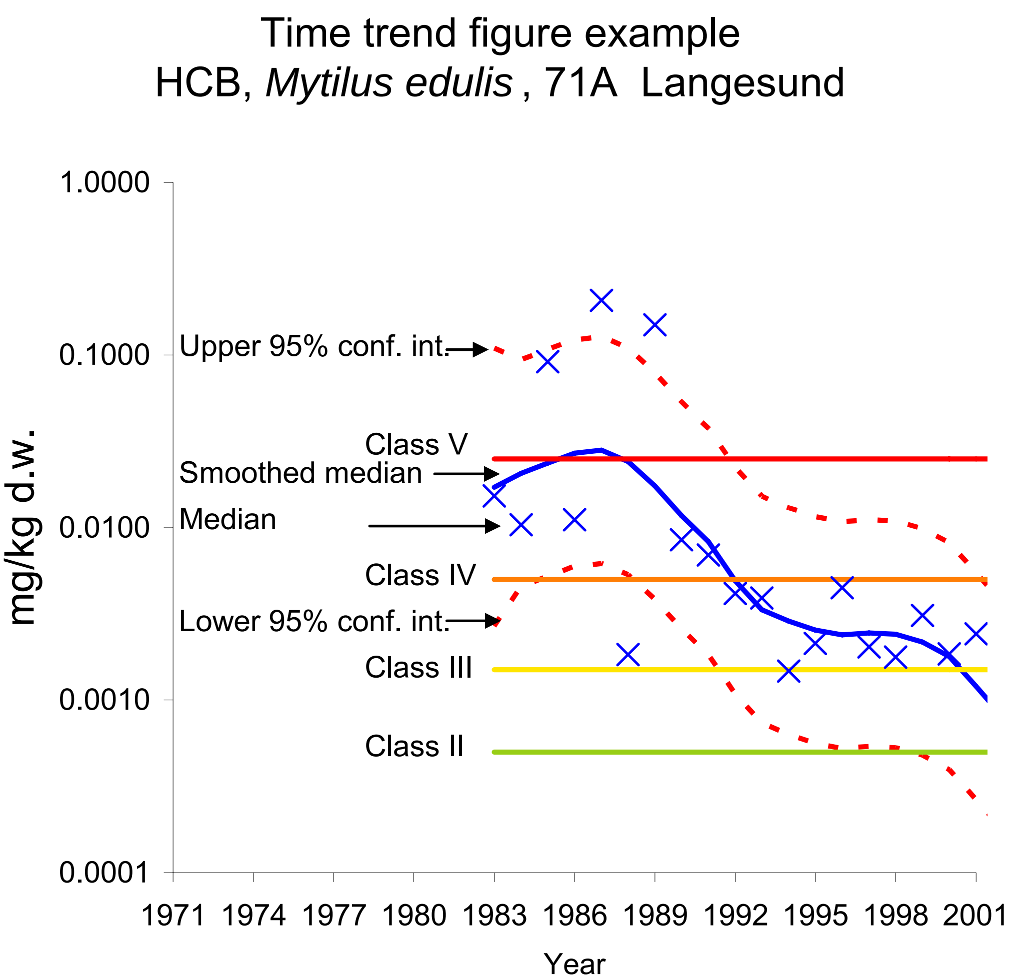

Figure 21. Example presentation and variation in contaminant concentration with time, indicating median concentrations, running mean of median values (Loess smoother), 95% confidence intervals. The horizontal lines indicate the lower boundaries to SFT classes of pollution: Class II (moderate=upper boundary to Class I (insignificant)), III (marked), IV (severe) and V (extreme), or alternatively the Class II boundary is replaced by the upper boundary to provisional "high background level" as in which case no class-boundaries are shown. (see text and refer to Table 7).

The method of calculating the smoother is in accordance to the methods employed at Ad Hoc Working Group on Monitoring that met in Copenhagen 23-27. February 1998 (MON 1998). A Loess smoother is based on a running seven-year interval, a non-parametric curve fitted to median log-concentrations (Nicholson *et al.*1997). For statistical tests based on a fitted smoother to be valid the contaminants indices should be independent to a constant level of variance and the residuals for the fitted model should be lognormally distributed (cf. Nicholson *et al.* 1998). No transformation was applied to the imposex (VSDI) data.

The National Comments since 1994 have included two additional analyses. The first is that the smoothed median for the last three sampling years is linearly projected for the next three years. This deviates from previous reports where the upper 95 confidence interval was used to assess the likelihood of overconcentrations (Nicholson, *et al.* 1994). The projected estimate is based on the results for the temporal trend analyses of at least 6 years of data.

The second is an estimate of the power of the temporal trend series expressed as the number of years to detect a 10% change per year with a 90% power (cf. Nicholson *et al.* 1997). The fewer the years the easier it is to detect a trend. The power is based on the percentage relative standard deviation (RLSD) estimated using the robust method described by ASMO (1994) and Nicholson *et al.* (1998). The estimate was made for series with at least 3 years of data and covers the *entire* period monitored. This fixed means of treating all the datasets may give misleading results especially where non-linear temporal changes are known to occur, such as for HCB in blue mussel from Langesundsfjord (Figure 4).

The statistical analysis was carried out on temporal trend data series for cadmium, mercury, lead, ΣPCB-7 (sum of congeners: 28, 52, 101, 118, 138, 153, 180), ppDDE (ICES code DDEPP), HCB, non-dicyclic PAHs, sum carcinogenic PAHs, B[*a*]P, TBT, and the biological effects parameters imposex (VSDI), PYR10, ALA-D and EROD-activity.

2.1.4. The effect of depuration and freezing on blue mussel

Based on samples collected in the Sørfjord and Hardangerfjord, the JAMP-method of pre-treatment of blue mussel (i.e., depuration and then cleaning) contrasted significantly to the Index-method (freezing then cleaning) (Green *et al.* 2001a). Using the JAMP-method, cadmium concentrations were significantly higher (24%), whereas significant lower concentrations were found for lead (45%), zinc (14%), PCBs (CB101, -118, -138, -153 27-52%) and DDTs (50-64%). Lower concentrations indicated that these contaminants are lost by depuration and gut emptying.

The results from a previous study from this region indicated no significant difference between the methods for mercury, cadmium, copper, lead and zinc (Green 1989). A study on blue mussel from the mouth of the Glomma River in Southern Norway showed that lead and copper were significantly lower in depurated samples (Green *et al.* 1996); however, no differences were found for PCBs or DDTs (on a lipid basis). The PCB concentrations found in the Glomma study were 3-4 times higher than Sørfjord/Hardangerfjord.

Mercury was the only contaminant common to all three studies that had consistent results; that there is no significant difference between the two methods.

The difference in methods has indicated an effect on the concentration of contaminants in blue mussel. However, with the exception of mercury, the results for Sørfjord/Hardangerfjord 2003 are inconsistent with two other studies in Norway. Revision of JAMP guidelines and assessment of data should take these results into consideration.

2.2. Information on Quality Assurance

NIVA has participated in all the QUASIMEME international intercalibration exercises, including Round 48. These exercises have included nearly all the contaminants analysed for JAMP. Quality assurance programme for NIVA is similar to the 2005 programme (cf. Green *et al.* 2007). In addition, NIVA was accredited in 1993 and since 2001 accredited in accordance with the NS-EN ISO/IEC 17025 standard by the Norwegian Accreditation (reference P009). A summary of the quality assurance programme at NIVA is given in Appendix A.

A recent investigation of measurements of certified references materiale from 1999-2006 for PCB indicated a systematic change in the analytical methods (Bakke *et al.* 2007b, Appendix A). This should be taken into consideration in the trend analyses.

2.3. Description of the Programme

The sampling for 2005 involved blue mussel at 61 stations, dogwhelk at 8, cod at 9 and flatfish at 11 stations (cf. Appendix E). The Norwegian JAMP has been expanded since 1989 to include monitoring in more diffusely polluted areas. Though new stations are initially intended for annual monitoring (temporal trends), there has not always been sufficient funds to do this for every station. Sample/station reduction measures have been taken to reduce costs. Furthermore, sufficient samples have not always been practical to obtain. When this applies to blue mussel, a new site in the vicinity is often chosen. As for fish, the quota of 25 individuals (±10%), indicated in Appendix E, as either 25 individuals or 5 bulked samples consisting of 5 fish per bulked sample, was met for all stations in 2005.

Concentrations of metals, organochlorines (including pesticides) and polycyclic aromatic hydrocarbons in blue mussel and fish were determined at the Norwegian Institute for Water Research (JAMP code NIVA).

Analytical methods have been described previously (Green *et al*. (2001b, Shi *et al.* 2008). An overview of the samples collected from 1981 to 2005 is given in Appendix E. An overview of analyses applied from 1981 to 2005 for biological material is given in Appendix C. Parameter abbreviations are given in Appendix B.

The data is stored at NIVA in MS ACCESS 1997. The tables are generated using MS ACCESS 97 and MS EXCEL 97.

Appendix A
Quality assurance programme

Accreditation

The laboratories at NIVA, both the chemical, microbiological and the ecotoxicological laboratories, were accredited in 1993 for quality assurance system by the National Measurement Service - Norwegian Accreditation and based on European Standard EN45000/ISO71EC Guide 25. NIVA has reference number P009. The chemical laboratoruim has satisfied the requirements in NS-EN ISO/IEC 17025 since 2001.

Summary of quality control results

Standard reference materials were analysed regularly (**Table 8** og **Table 9**). Dogfish muscle (DORM-2) or dogfish liver (DOLT-3) was used as SRM for the control of the determination of metals. Cod liver oil (1588) and mussel tissue (2977) was used as SRM for controls of PCBs and PAHs, respectively. NIES 11 was used for tin organic compounds. Cyprinid fish (EDF2525) at NILU was used as SRM for control of determination of dioxins. For sediments, MESS-3 was used as SRM for trace metals, and the SRM 1944 for the determination of selected polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyl (PCB) congeners, and chlorinated pesticides.

Following results for round Quasimeme –Round 48 were used. This round would apply to the 2006 samples:

- QTM073BT (no.1) and QTM074BT (no.2) for metals in biota.
  The results were acceptable (z-scores between -2 and 2), except for one result which was classified as questionable (z-scores between -3 and 3), and this was Selenium in sample no.1.
- QOR090BT (no.1) and QOR091BT (no.2) for organochlorines in biota.
  The results were acceptable except for four results which were classified as questionable, and these were CB101, CB118 and HCB from sample no.1 and CB52, from sample no.2. It can be noted that several samples had generally very low concentrations of PCBs.
- QPH045BT and QPH046BT for PAH in biota.
  The results were acceptable except for questionable results for benzo[b]fluoranthene .This is likely due to that results submitted included benzo[j]fluoranthene which, by the methods currently in use, can not be distinguished from the former PAH-compound.

- QTM078MS (no.1) and QTM079MS (no.2) for metals in sediments.
  All results were acceptable (z-scores between -2 and 2).
- QOR088MS (no.1) and QOR089MS (no.2) for organochlorines in sediments.
  The results were acceptable (z-scores between -2 and 2), except for two results which was classified as questionable and these were CB180 and pp`DDD in sample no.2.
- QPH052MS (no.1) and QPH053MS (no.2) for PAH in sediments.
  Ten of the results were not acceptable and the samples were reanalysed. Four of the reanalysed results were not satisfactory. One of these were benzo[b]fluoranthene .This is likely due to that results submitted included benzo[j]fluoranthene which, by the methods currently in use, can not be distinguished from the former PAH-compound. The other three were benzo[e]pyrene, indeno[1,2,3-cd]pyrene and dibenz[a,c+a,h] anthracene which were classified as questionable (z-scores between -3 and 3).

Table 8. Summary of the quality control of results for the 2006 biota samples analysed in 2006-2007. The Standard Reference Materials (SRM) were DORM-2* (dogfish muscle) for blue mussel and fish fillet, DOLT-3* (dogfish liver) for fish liver, 1588** (cod liver oil) for blue mussel and fish liver and 2977** (mussel tissue) for blue mussel. SRM was analysed in series with the JAMP-samples for analyses of metals (mg/kg d.w.), NIES 11 for organochlorines or PAH (µg/kg d.w.) and EDF2525**** for fish (cyprinid) was analysed for dioxin(ng/kg) by NILU (Norwegian Institute for Air Research – results for 2005 material are shown here; cf. Green *et al.*2005). Tissue types were: mussel softbody (SB), fish liver (LI) and fish fillet (MU). SRMs were measured several times (N) over a number of weeks (W).

Table 9. Summary of the quality control of results for the 2006-2007 sediment samples analysed in 2006-2007. The Standard Reference Materials (SRM) were MESS-3 for trace metals in marine sediment (mg/kg d.w) and 1944 for the determination of selected polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyl (PCB) congeners, chlorinated pesticides, and trace elements (µg/kg d.w) in marine sediment. These SRM were analysed in series with the JAMP-samples for analyses of metals and the organic compounds.

Comment on quality control results

In connection with a reanalysis of stored samples, a 7 year time series of PCB values for control sample analyses have been statistically analysed (**Figure 22**, Bakke *et al.* 2007b). The results show that the short term (within-day) fluctuations of values relative to the certified values has a standard deviation of about 7 % as RMS average over 6 components. In addition, there is a long-term variation; the variation between yearly averages have a standard deviation of about 9 %, and there is also a medium-term variation (within-year, between-days) of about the same size. The combined standard deviation is about 14 %. The between-year variation is not merely random fluctuations, but has a systematic pattern, with the first 1-2 years having generally larger values than the rest of the period, this indicates systematic changes in analysis procedures that might need to be taken into consideration in time trend analysis.

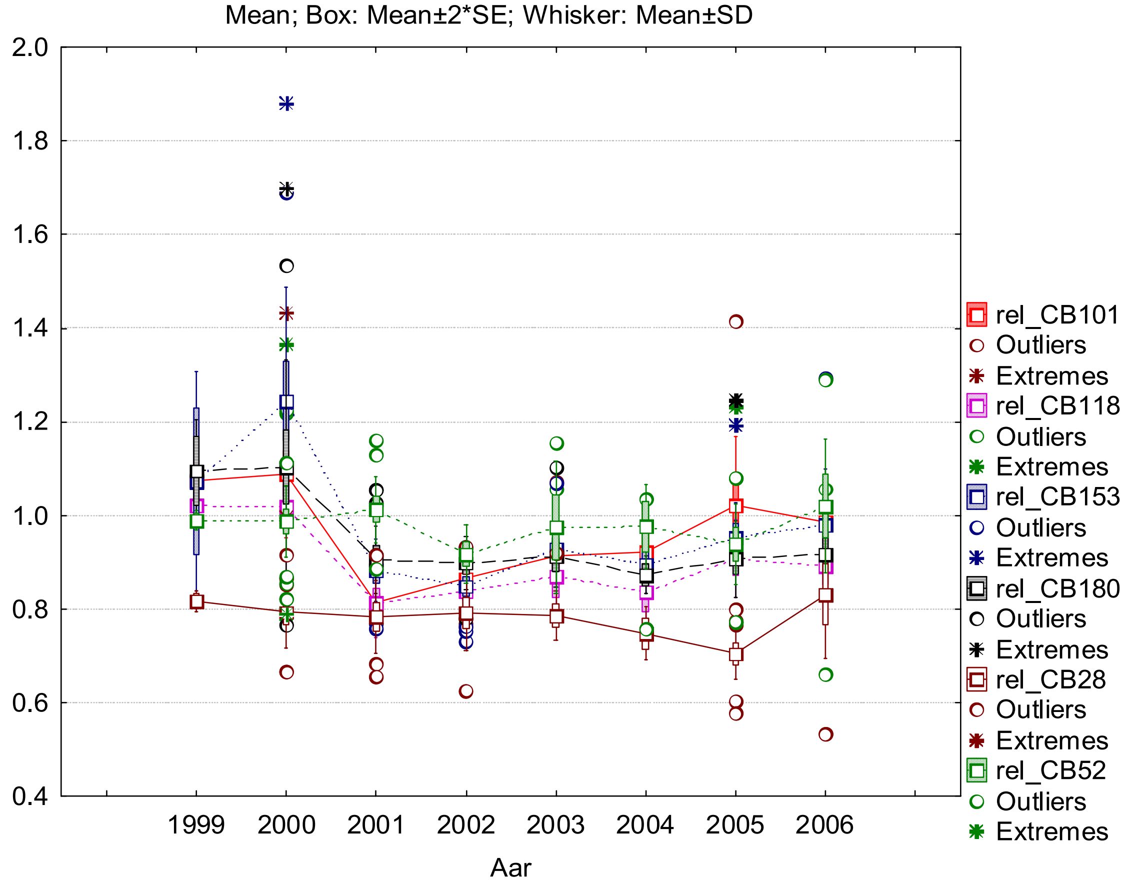

Figure 22. Measurements of CRM relative to certified values for 7 PCB congeners 1999-2006. Outliers are value >mean+8*SE or <mean-8*SE; and Extremes are values >mean+14*SE or <Mean-14*SE; where SE is Standard error of the mean. Analysis done using data analysis software system STATISTICA (version 7.1, StatSoft, Inc. (2006), www.statsoft.com).

[1]) After: ICES Environmental Data Reporting Formats. International Council for the Exploration of the Sea. July 1996 and supplementary codes related to non-ortho and mono-ortho PCBs and “dioxins” (ICES pers. comm.)

[2]) Indicates "PAH" compounds that are dicyclic and not truly PAHs typically identified during the analyses of PAH, include naphthalenes and "biphenyls".

[3]) Indicates the sum of tri- to hexacyclic PAH compounds named in EPA protocol 8310 minus naphthalene (dicyclic), so that the SFT classification system can be applied

[4]) Indicates PAH compounds potentially cancerogenic for humans according to IARC (1987, updated 14.August 2007 at http://monographs.iarc.fr/ENG/Classification/crthgr01.php), i.e., categories 1, 2A, and 2B (are, possibly and probably carcinogenic). NB.: the update inlcludes Chrysene as cancerogenic and hence, KPAH with Chrysene should not be used in SFT’s classification system for this sum-variable (Molvær *et al.* 1997).

[5]) Indicates non ortho- co-planer PCB compounds i.e., those that lack Cl in positions 1, 1', 5, and 5'

Appendix D
Participation in intercalibration exercises

Appendix D1

Participation in intercalibration exercises other than QUASIMEME

Sea water:

4H ICES/JMG Fifth Round Intercalibration on Trace Metals in Sea Water - Section 4, analysis for Hg - 1983 - (5/TM/SW:4).

4I JMG Sixth Intercalibration on Trace Metals in Estuarine Waters - 1986 - (6/TM/SW).

4Z Intercalibration exercise for SIIF/SERI (Cd) and NIVA/IAMK (IAMK=Chalmers Inst., Göteborg) - 1985.

Seabed sediment:

7E ICES, First Intercalibration Exercise on Trace metals in Marine Sediments - 1984 - (1/TM/MS).

8B ICES/OSPAR, First Intercomparison Exercise on Organochlorines (individual chlorobiphenyl congeners) in Marine Sediments - Phase 1, analysis of standard solutions - 1989 - (1/OC/MS:1).

8C ICES/OSPAR, First Intercomparison Exercise on Organochlorines (individual chlorobiphenyl congeners) in Marine Sediments - Phase 2, analysis of standard solutions - 1991 - (1/OC/MS:2).

8B ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 1 - (analysis of standard solutions) - 1989 - (1/OC/MS-1).

8C ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 2 - 1990 - (1/OC/MS-2).

8D ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 3a (1/OC/MS-3a) 1991.

8E ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 3b - (1/OC/MS-3b) 1992.

8F ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 4 - (1/OC/MS-4) 1993.

Marine biota:

1E ICES, Fifth Intercalibration Exercise on Trace Metals in Biological Tissues - 1978 - (5/TM/BT).

1F ICES, Sixth Intercalibration Exercise on Trace Metals (Cadmium and Lead only) in Biological Tissues - 1979 - (6/TM/BT).

1G ICES, Seventh Intercalibration Exercise on Trace Metals in Biological Tissues - Part A - 1983 - (7/TM/BT).

1H ICES, Seventh Intercalibration Exercise on Trace Metals in Biological Tissues - Part B - 1985 - (7/TM/BT) (preliminary report 1987).

1Z VETN Interlabcalibration exercise with VETN and SIIF 1983, mercury and cadmium in cod filet and liver.

1Z NIVA	Interlabcalibration exercise with VETN, NACE and NIVA 1986 (Hg, Cd, Cu, Pb and Zn in 6 samples).
2D	ICES Fourth Intercalibration Exercise on Organochlorines (mainly PCBs) in Biological Tissues (Sample No.5) - 1979 - (4/OC/BT).
2E	ICES Fifth Intercalibration Exercise on Organochlorines (PCBs only) in Biological Tissues - 1982 - (5/OC/BT).
2G	ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 1 - (analysis of standard solutions) - 1989 - (7/OC/BT-1).
2H	ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 2 - 1990 - (7/OC/BT-2).
2I	ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 3a - (7/OC/BT-3a) 1991.
2J	ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 3b - (7/OC/BT-3b) 1992.
2K	ICES/IOC/OSPAR Intercomparison Programme on the Analysis of Chlorobiphenyls in Marine Media - Step 4 - (7/OC/BT-4) 1993.
2Z VETN	Interlabcalibration exercise with VETN among others, 1983, PCB and HCB in cod liver.
2Z NACE	Interlabcalibration exercise with NACE, VETNand SIIF 1986 (PCB (all labs), DDE, OCS, HCB and DCB (NACE and VETN).

Appendix F
Overview of localities and sample count for biota 1981-2006

Nominel station positions are shown on maps in Appendix G

jmpco: JAMP area code (J99 = unclassified)
jmpst: station code
stnam: station name
nom_lon: Longitude (nominel)
nom_lat: Latitude (nominel)
speci: species code (English, Norwegian (Latin))

- MYTI EDU - blue mussel, blåskjell (*Mytilus edulis*)
- NUCE LAP - dogwhelk, purpursnegl (*Nucella lapillus*)
- BROS BRO - tusk, brosme (*Brosme brosme)*
- CHIM MON - rat fish, havmus (*Chimaera monstrosa*)
- GADU MOR - Atlantic cod, torsk (*Gadus morhua*)
- LEPI WHI - megrim, glassvar (*Lepidorhombus whiff-iagonis*)
- LIMA LIM - dab, sandflyndre (*Limanda limanda*)
- MICR KIT - lemon sole, lomre (*Microstomus kitt*)
- MOLV MOL - ling, lange (*Molva molva*)
- PAND BOR - shrimp, reker (*Pandalus borealis)*
- PLAT FLE - flounder, skrubbe (*Platichthys flesus*)
- PLEU PLA - plaice, rødspette (*Pleuronectes platessa*)

tissu: tissue:
SB - soft body
LI - liver
MU - fillet
TM - tail muscle

Appendix G
Map of stations

Nominel station positions 1981-2006
(cf. Appendix H and Appendix L)

Appendix G (cont.) Map of stations

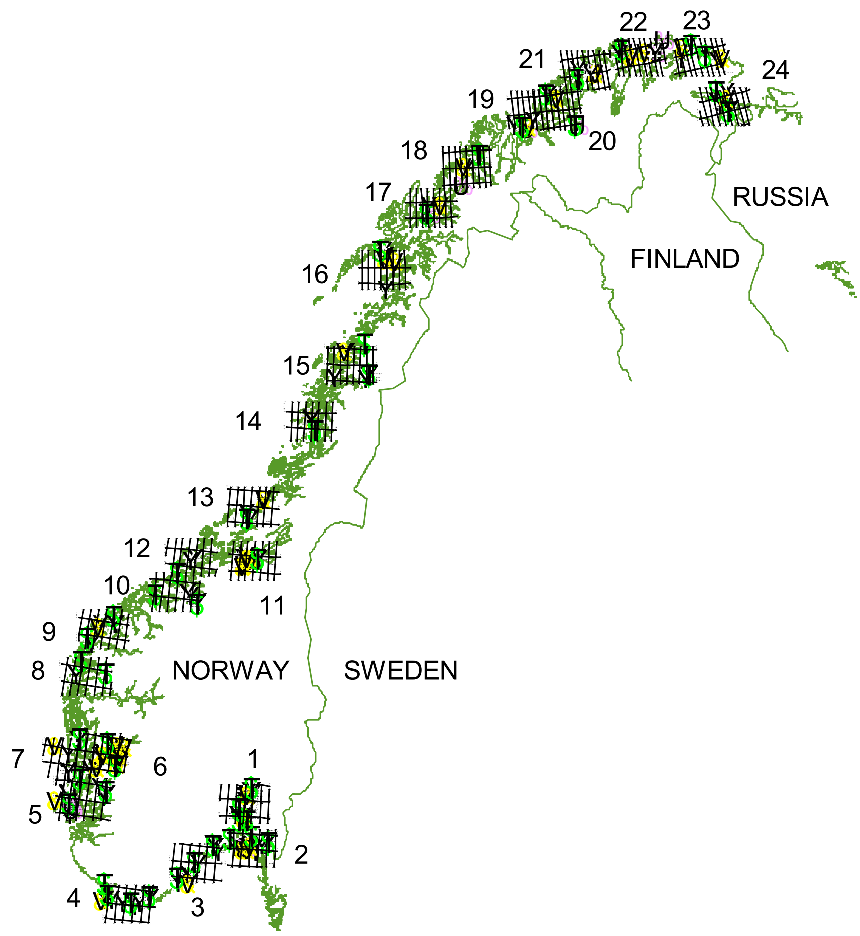
NOTES

The station's nominal position is plotted, and not the specific positions that may have differed from one year to another. The maps are generated using ArcGIS version 9.1.

The following symbols and codes apply:

All years	2006	Explanation	Station code
		Sediment	<number>S
		Bluemussel	<number>A
		Bluemussel	I<number/letter> [1)]
		Bluemussel	R<number/letter> [1)]
		Dogwhelk	<number>F
		Prawn	<number>C
		Atlantic cod	<number>A
		Flatfish	<number>D/E
		Other round fish	
		Town or city	

1) Supplementary station used in SFT bluemussel pollution (I) or reference (R) index (cf. Appendix L).



JAMP stations Norway. Numbers indicate map reference that follow.
Note: distance between two lines of latitude is 15 nautical miles (= 27.8 km).

Appendix I
Temporal trend analyses of contaminants and biomarkers in biota 1981-2006

Sorted by contaminant, species and area/station:

Cadmium (Cd)
Mercury (Hg)
Lead (Pb)
Copper (Cu)
Zinc (Zn)
Sum PCB-7 or CB_S7 (CB: 28+52+101+118+138+153+180)
DDEPP (ppDDE)
HCB
BAP (benzo[*a*]pyrene)
PK-Σn or PK_S (sum carcinogen PAHs, cf. Appendix B)
P-Σn or P_S (sum of PAHs, dicyclic "PAHs" not included, cf. Appendix B)
TBT (Tributyltin)
TCDDN (Dioxin toxicity equivalents – Nordic model)
ALA-D (δ-amino levulinic acid dehydrase inhibition)
EROD-activity (Cytochrome P4501A-activity)
CYP1A (relative amount of Cytochrome P4501A protein)
OH-pyrene or PYR10 (Pyrene metabolite)
VDSI (measurement of imposex)

JAMP-stations
"Index"-stations
MYTI EDU - Blue Mussel (*Mytilus edulis*)
NUCE LAP – Dog whelk (*Nucella lapillus*)
GADU MOR - Atlantic cod (*Gadus morhua*)
LEPI WHI - Megrim (*Lepidorhombus whiff-iagonis*)
LIMA LIM - Dab (*Limanda limanda*)
PLAT FLE - Flounder (*Platichthys flesus*)
(s) - Small fish
(l) - Large fish

Tsu -tissue:
SB - Soft body tissue
LI - Liver tissue
MU - Muscle tissue
BL - Blood
BI - Bile

OC	**Overconcentration expressed as quotient of median of last year and "high background" ("?" missing background value)**	
TRD	**trend**	
	D-	**Significant linear trend, downward**
	U-	**Significant linear trend, upward**
	--	**No significant trend**
	-?	**No significant linear trend, systematic non-linear trend can not be tested because of insufficient data (<6 years)**
	-Y	**No significant linear trend, but a systematic non-linear trend**
	DY or UY	**Significant linear trend (downward or upward) and a significant non-linear trend. This is considered the same as "-Y"**
	SIZE length effect (mercury in fillet)	
	L	**Significant difference in concentration levels but pattern of variation same**
	D	**As "L" but pattern of variation significantly different**
	-	**No significant difference between "small" and "large" fish**
SM3	**Projected smoothed median for three years expressed as quotient of value and "high background" ("?" if missing background or if number of years is less than seven)**	
PWR	**POWER; estimated number of years to detect a hypothetical situation of 10% trend a year with a 90% power**	

Note on detection limit: for values designated below detection limit, half of this limit is used.

Annual median concentration of CD (ppm)

Appendix J
Geographical distribution of contaminants and biomarkers in biota 1990-2006

Sorted by contaminant and species:

Cadmium (Cd)
Mercury (Hg)
Lead (Pb)
Sum of 7 CBs (CB-28, -52, 101, -118, -138, -153 and -180)
DDEPP (ppDDE)
HCB
TCDDN
BDE
OH-pyrene
ALA-D (δ-amino levulinic acid dehydrase inhibition)
EROD-activity (Cytochrome P4501A-activity)
CYP1A (relative amount of cytochrome P4501A-protein)
TBT
VDSI

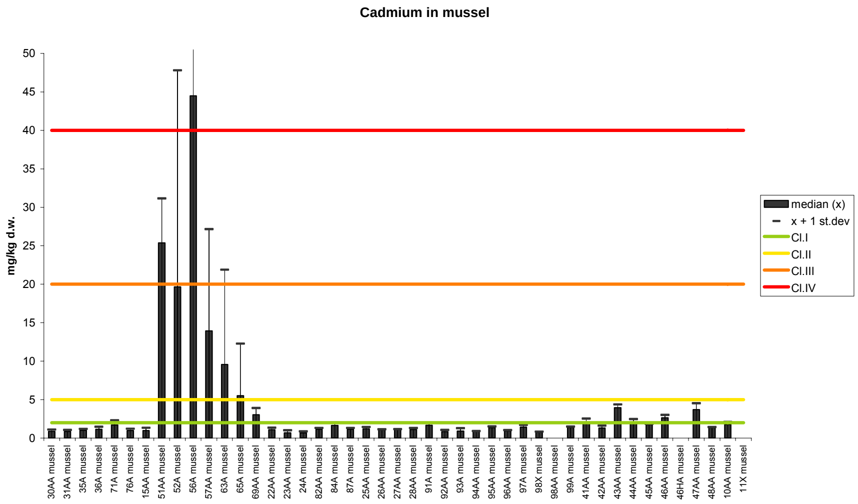
MYTI EDU - Blue Mussel (*Mytilus edulis***)**
GADU MOR - Atlantic cod (*Gadus morhua***)**
PLAT FLE - Flounder (*Platichthys flesus***)**
LIMA LIM - Dab (*Limanda limanda***)**
PLEU PLA - Plaice (*Pleuronectes platessa***)**
MICR KIT - Lemon sole (*Microstomus kitt***)**
LEPI WHI - Megrim (*Lepidorhombus whiff-iagonis***)**

Station positions are shown on maps in Appendix G

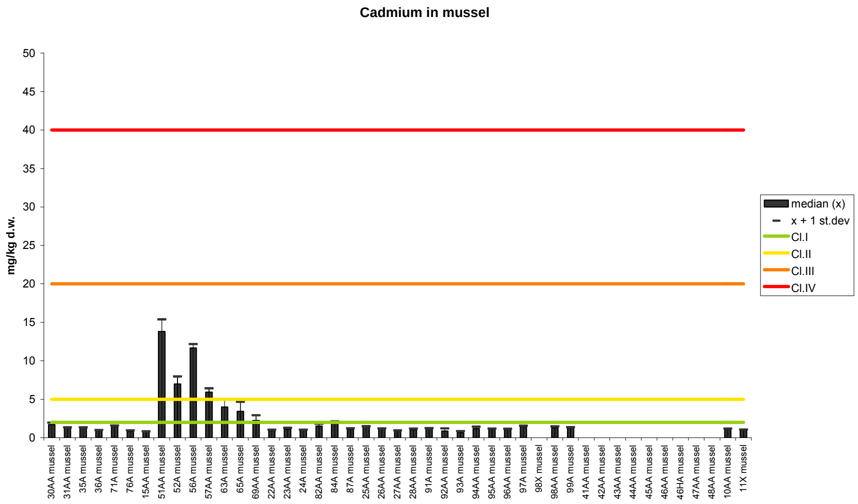
Results are presented for three periods: 1990-1996, 2005 and 2006.
The average median concentrations was used for each period. Cf. Appendix E.

Appendix J
Geographical distribution of contaminants and biomarkers in biota 1990-2006
(cont.)

A



B



C

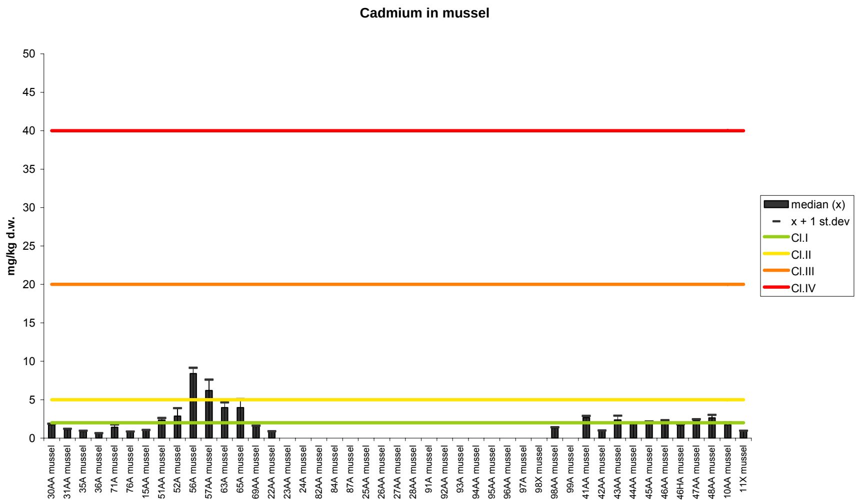


Figure 23. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for cadmium in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight (see maps in Appendix G). **Note: for some stations the standard deviation is off-scale in figures A.**

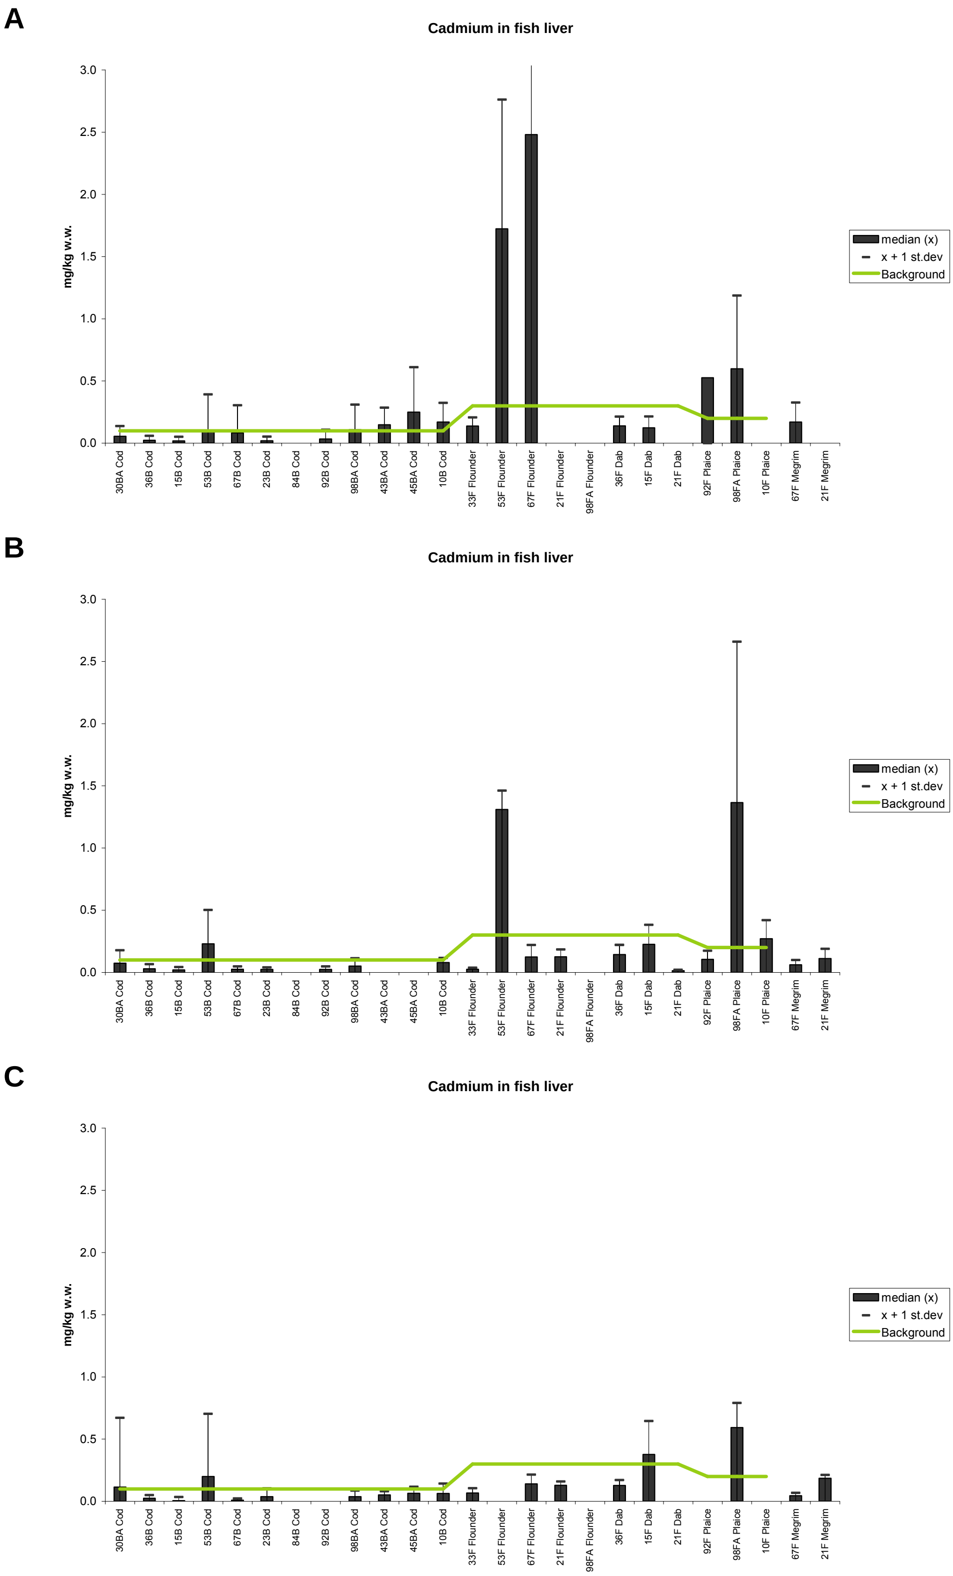

Figure 24. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for cadmium in fish liver 1990-1996 **(A),** 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight, "Cl. – B" indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for all fish, (see maps in Appendix G).

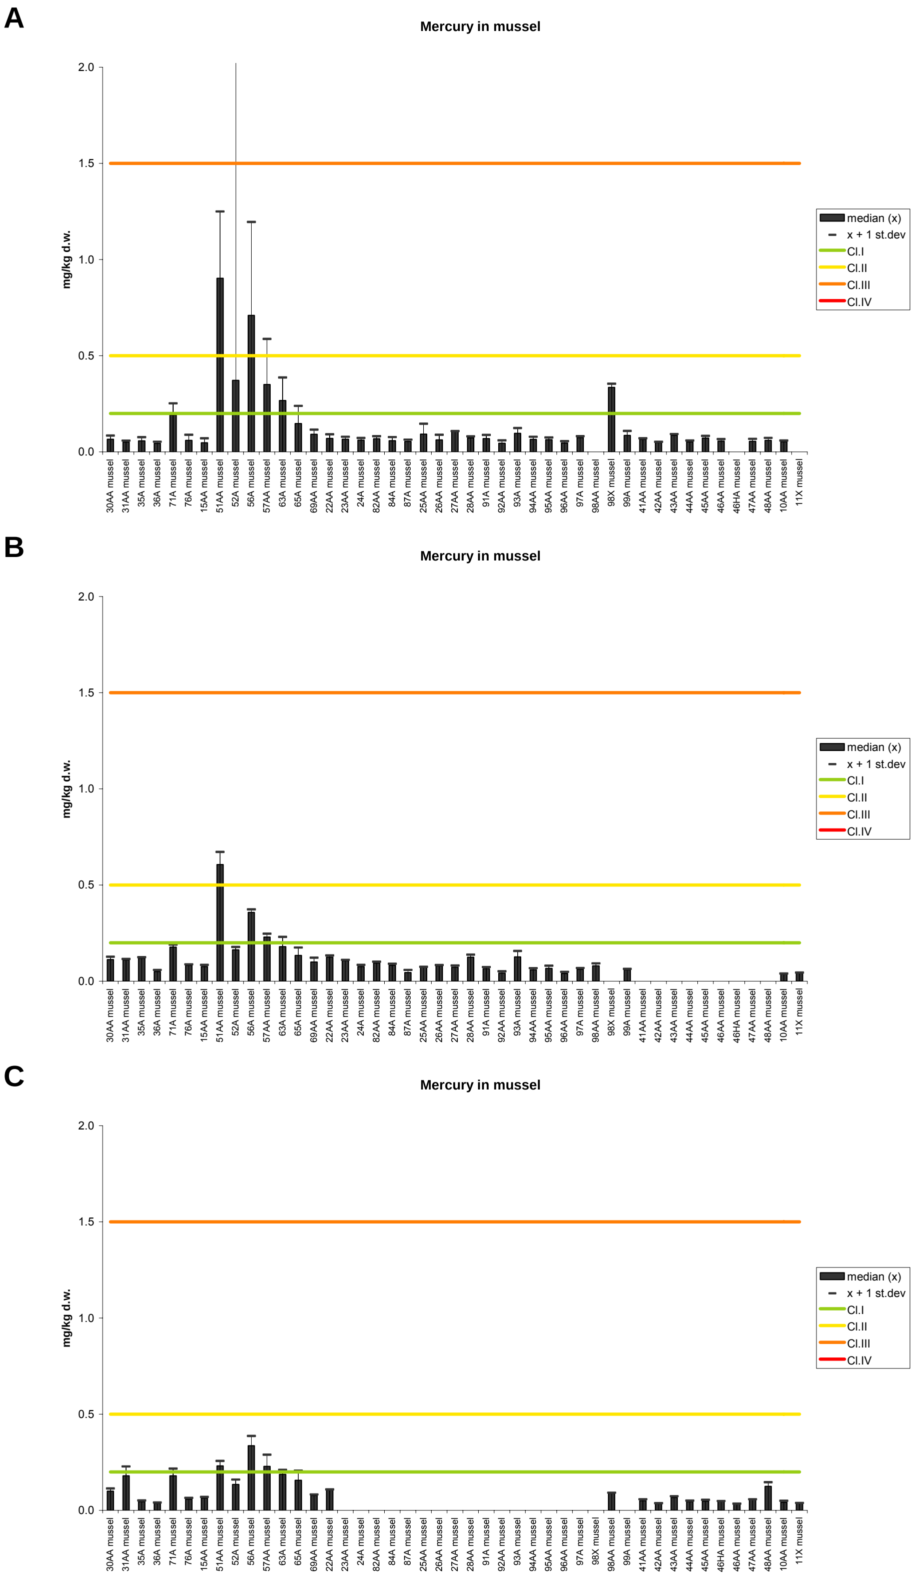

Figure 25. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for mercury in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight (see maps in Appendix G).

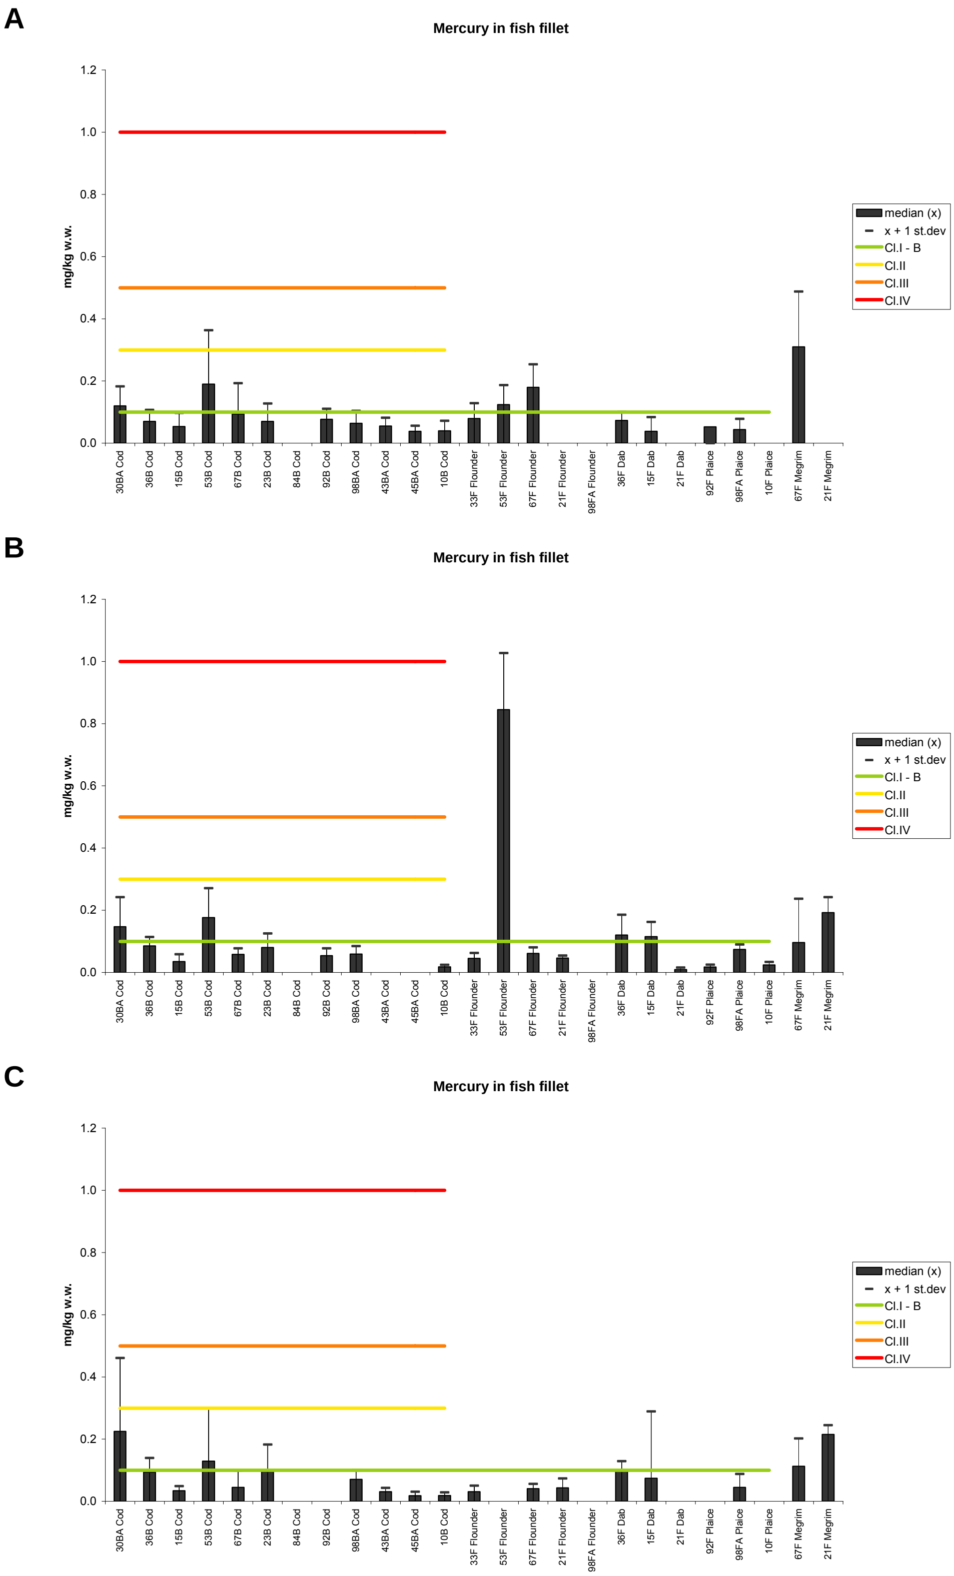

Figure 26. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for mercury in fish fillet 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight, “Cl. – B” indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for flatfish, (see maps in Appendix G).

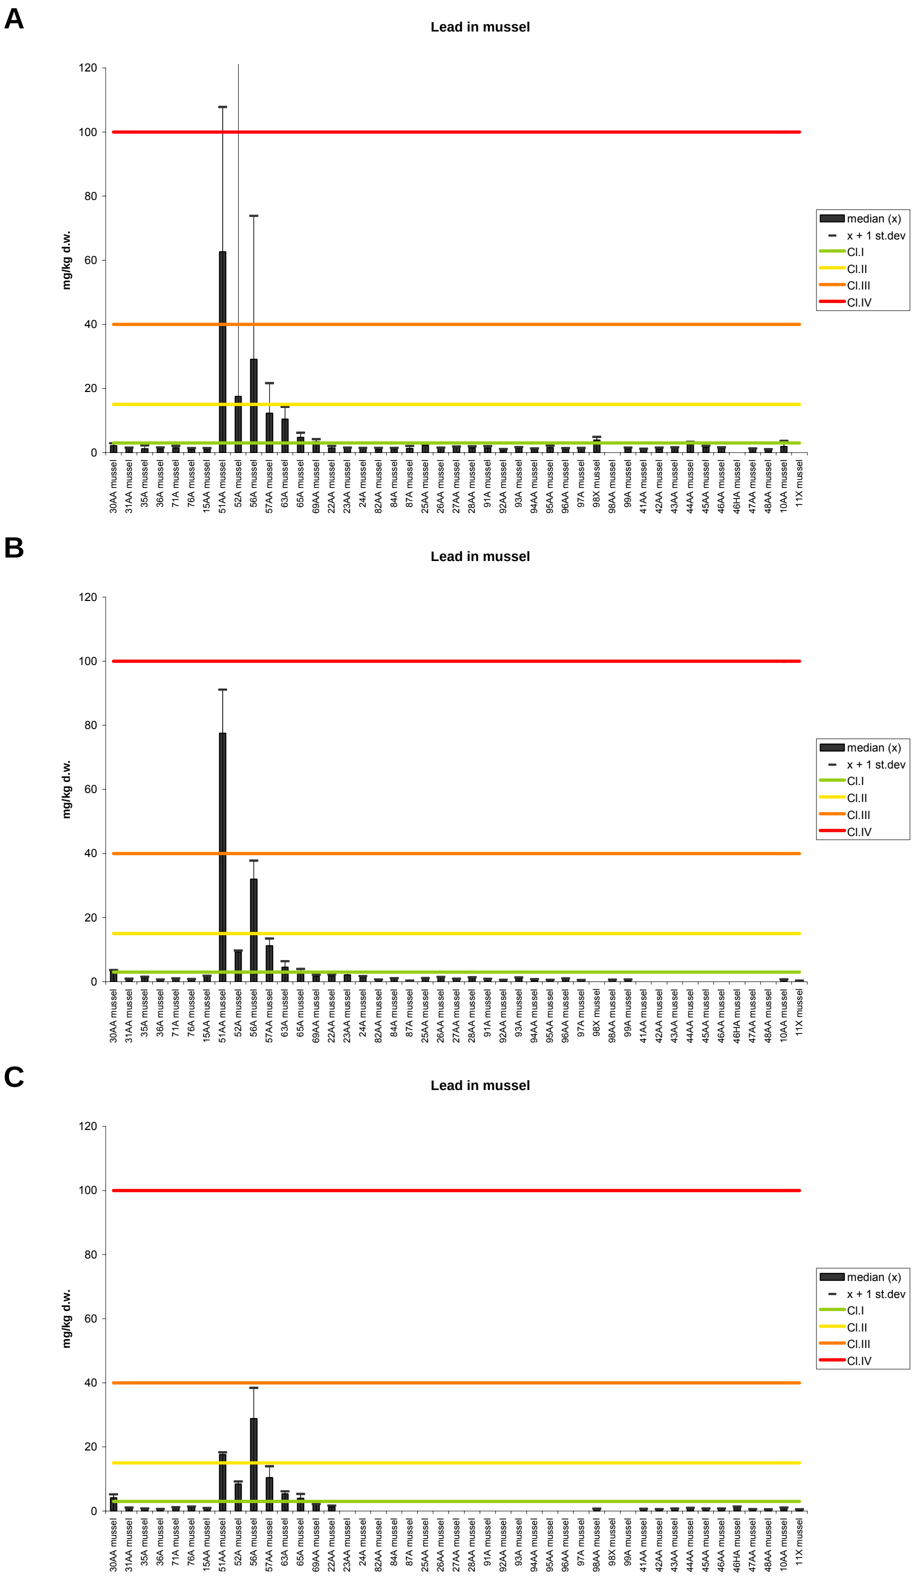

Figure 27. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for lead in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight (see maps in Appendix G). **Note: for some stations the standard deviation is off-scale in figure A.**

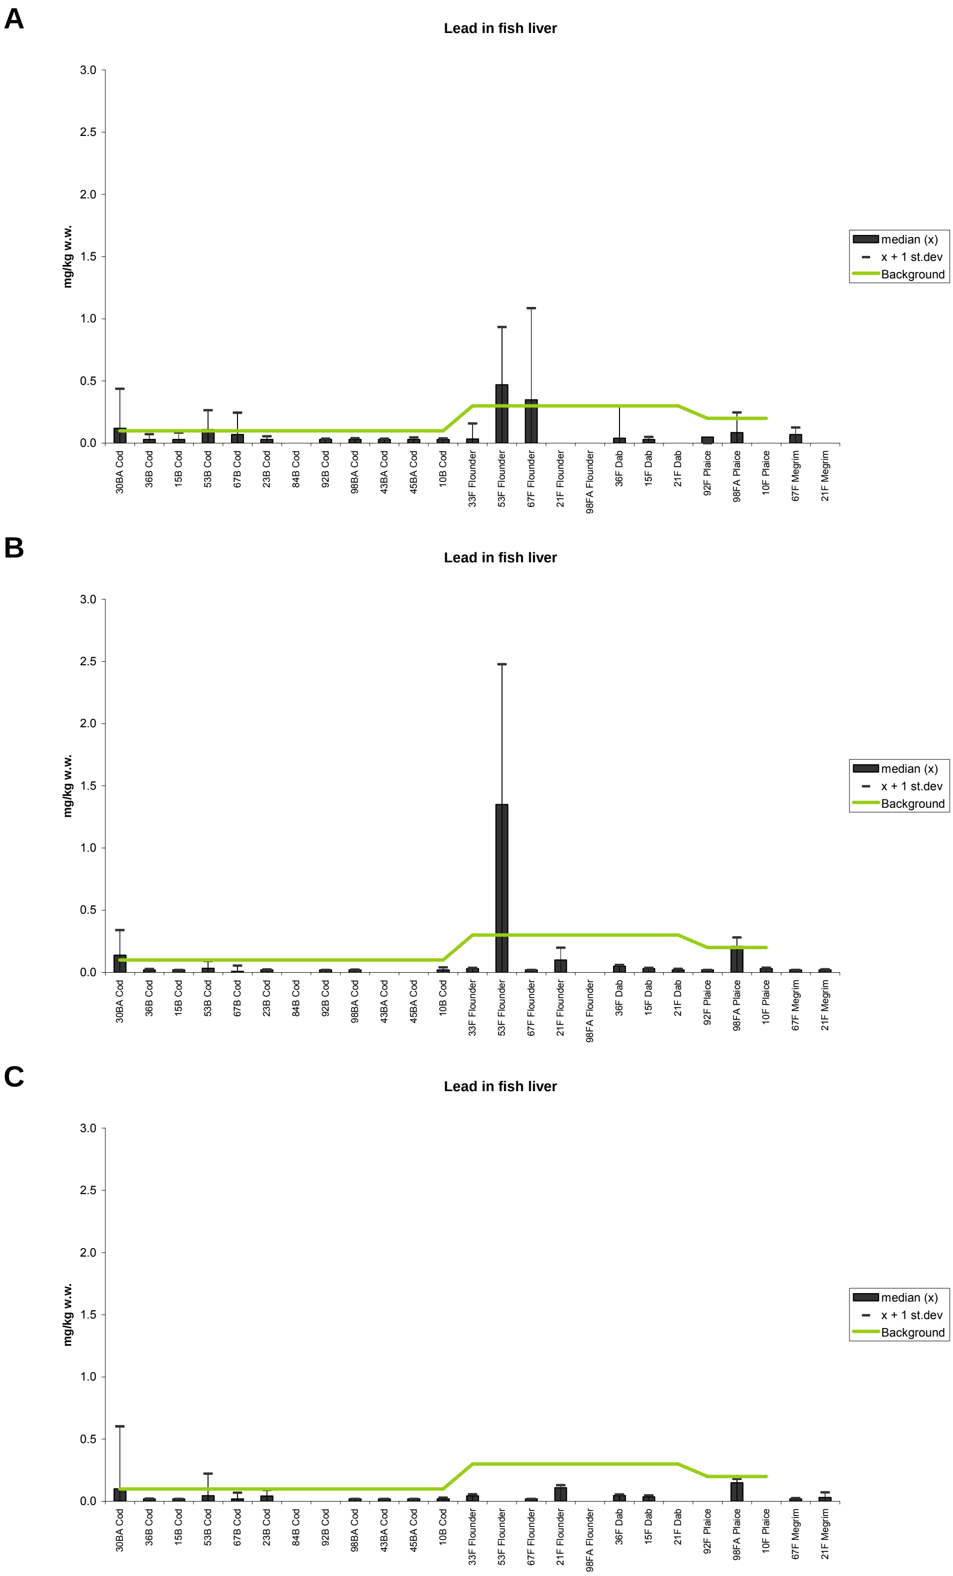

Figure 28. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for lead in fish liver 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppm (mg/kg) wet weight, "Cl. – B" indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for all fish, (see maps in Appendix G).

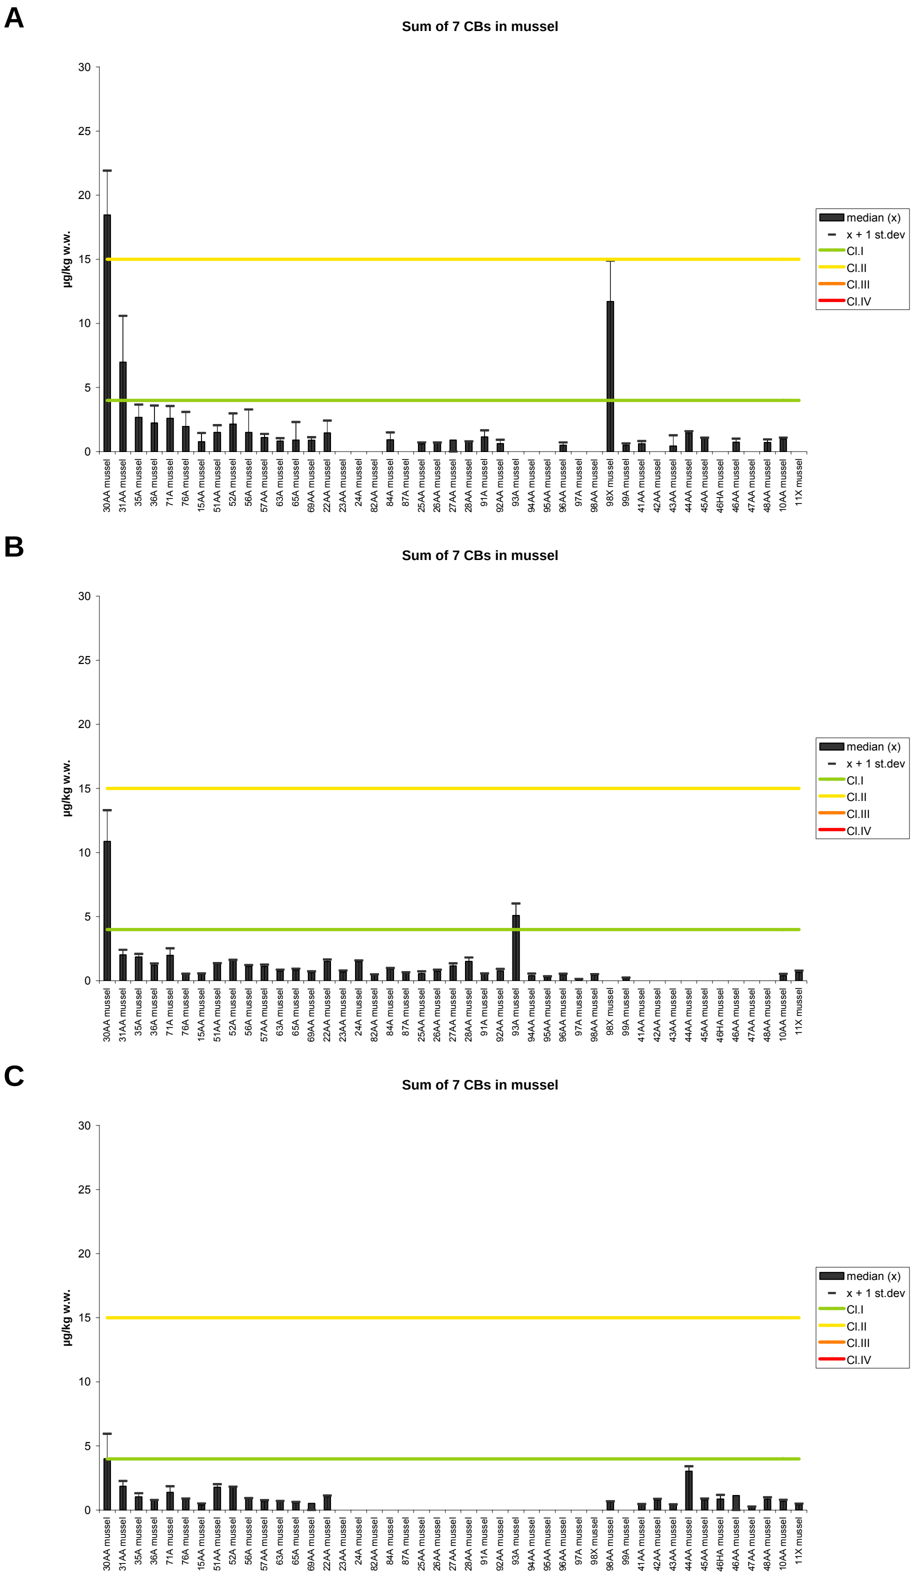

Figure 29. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for sum of 7 PCBs (CB-28, -52, 101, -118, -138, -153 and -180) in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight (see maps in Appendix G).

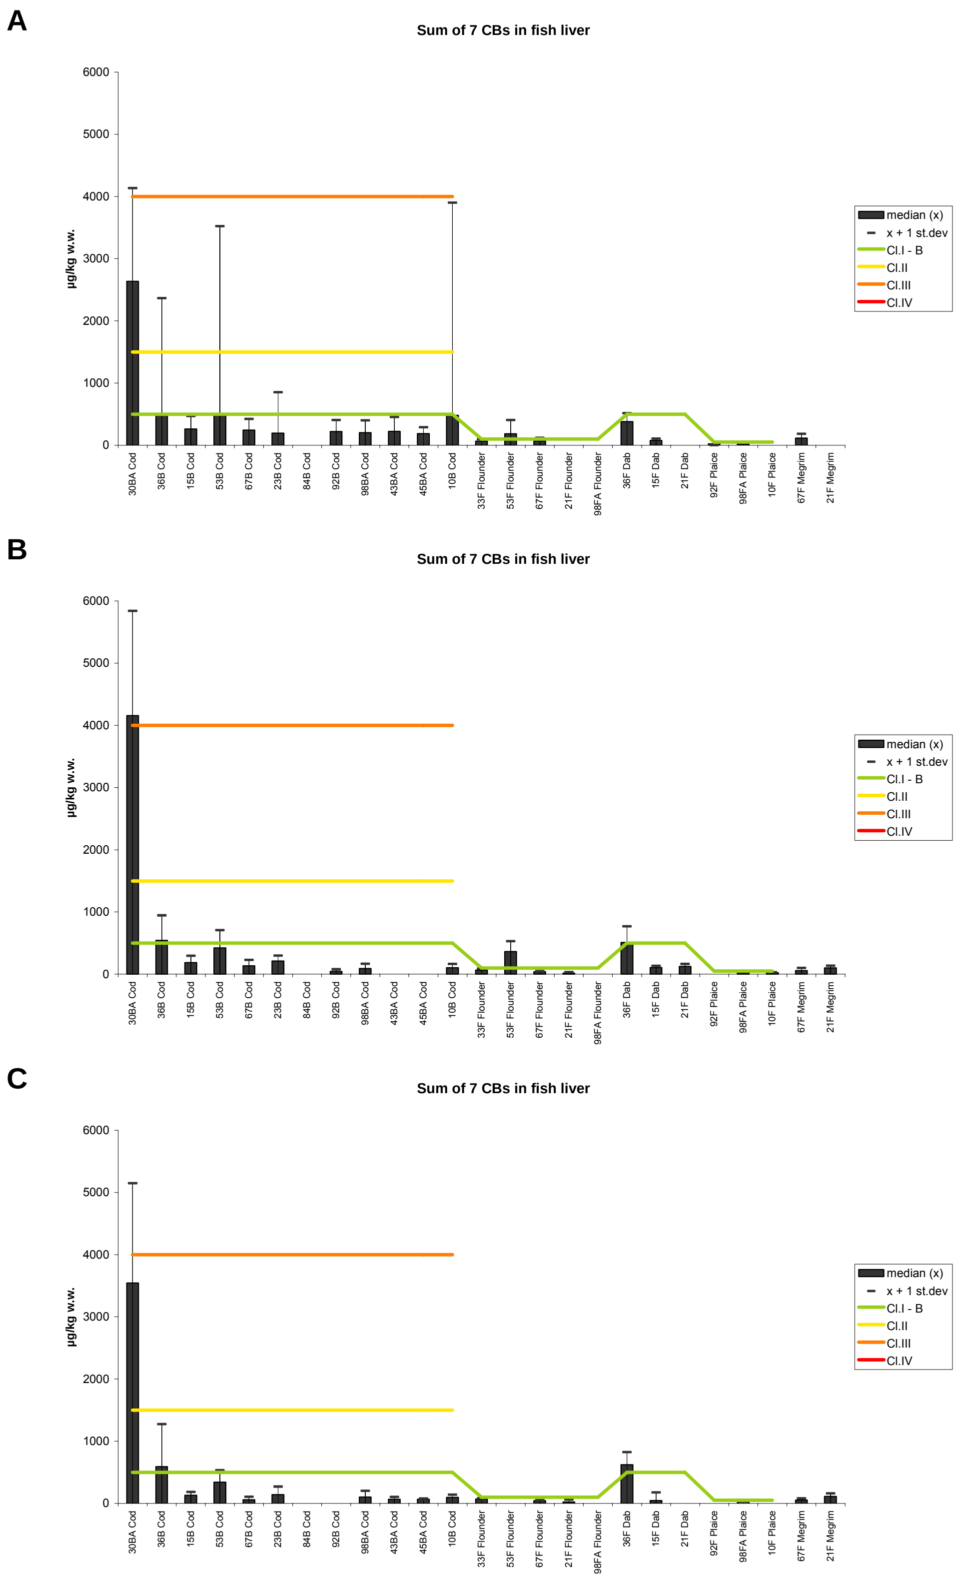

Figure 30. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for sum of 7 PCBs (CB-28, -52, 101, -118, -138, -153 and -180) in fish liver 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight, "Cl. – B" indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for flatfish, (see maps in Appendix G). **Note: for some stations the standard deviation is off-scale in figures A-C.**

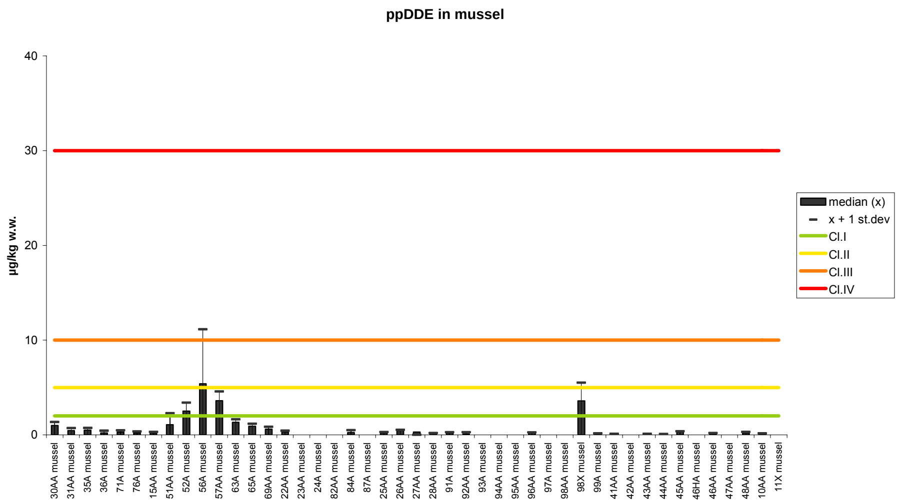
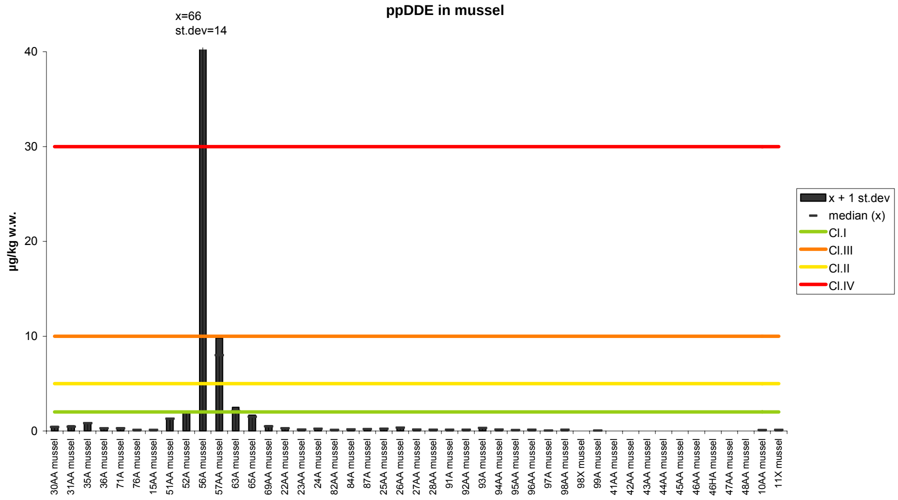
A



B



C

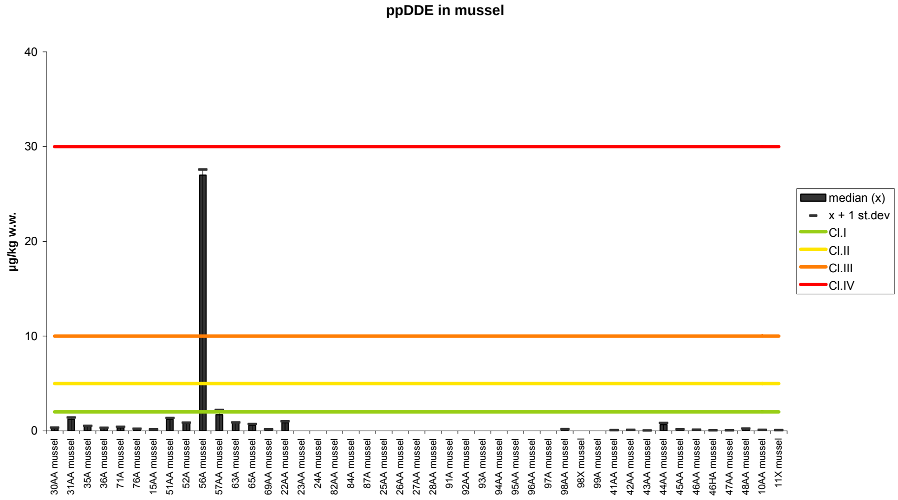


Figure 31. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for ppDDE (DDEPP) in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight (see maps in Appendix G). (See also footnote in Table 7). **Note: Class limits for ΣDDT used, and for some stations the standard deviation is off-scale in figure B.**

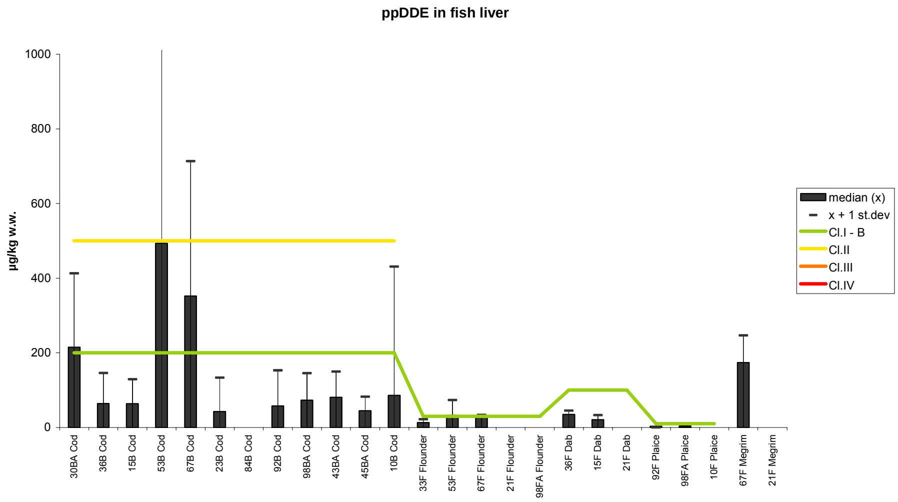
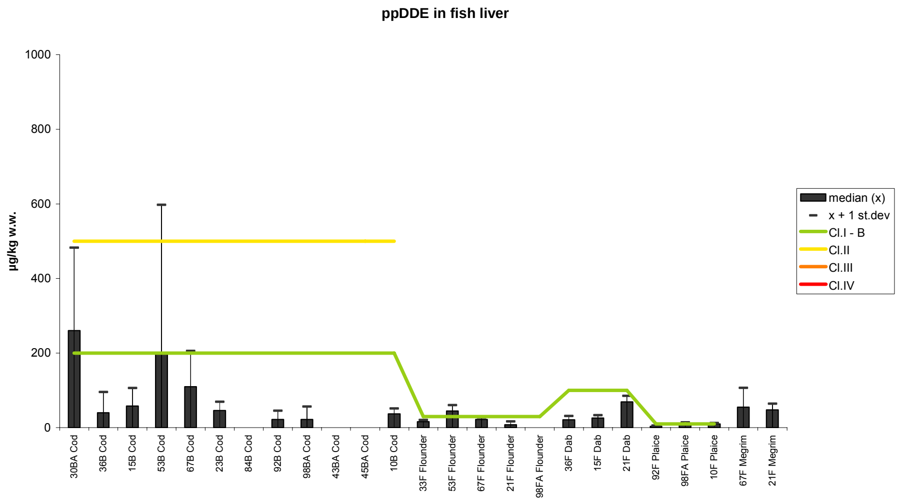
A



B



C

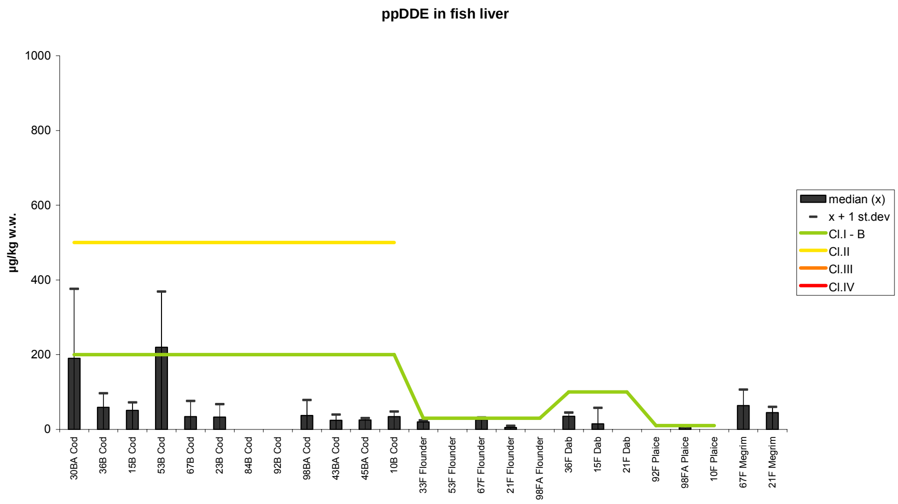


Figure 32. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for ppDDE (DDEPP) in fish liver 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight, "Cl. – B" indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for flatfish, (see maps in Appendix G). (See also footnote in Table 7). **Note: Class limits for ΣDDT used**

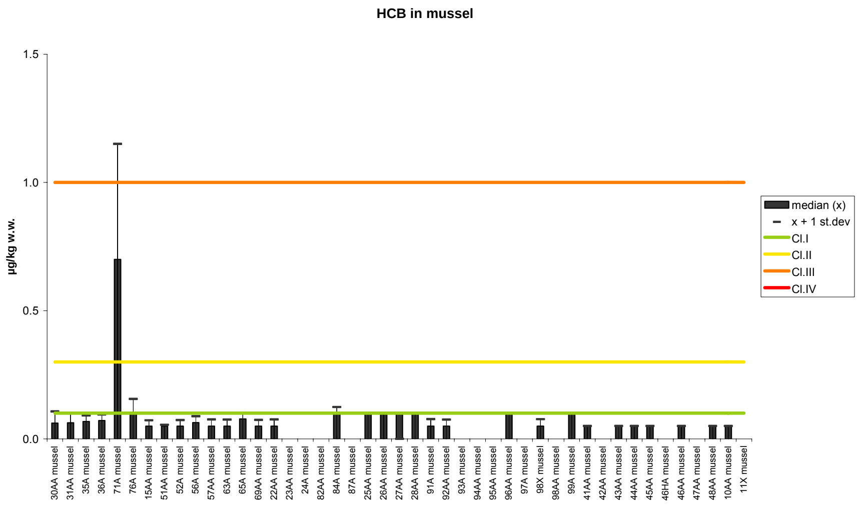
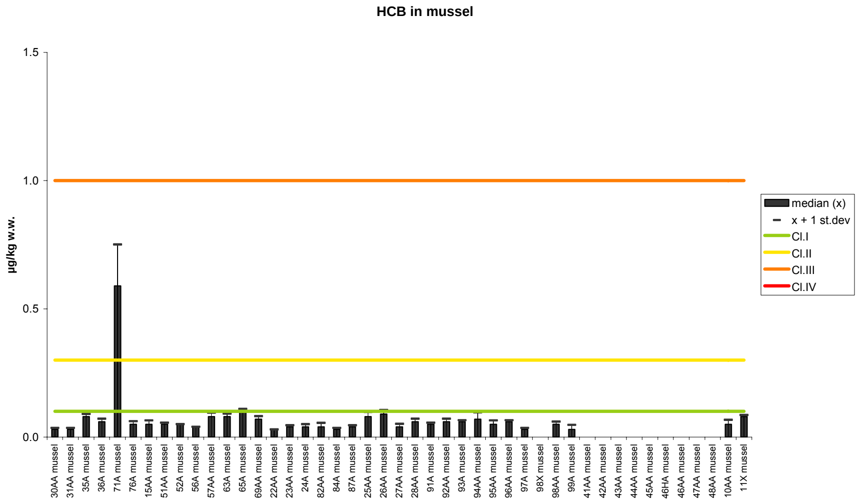
A



B



C

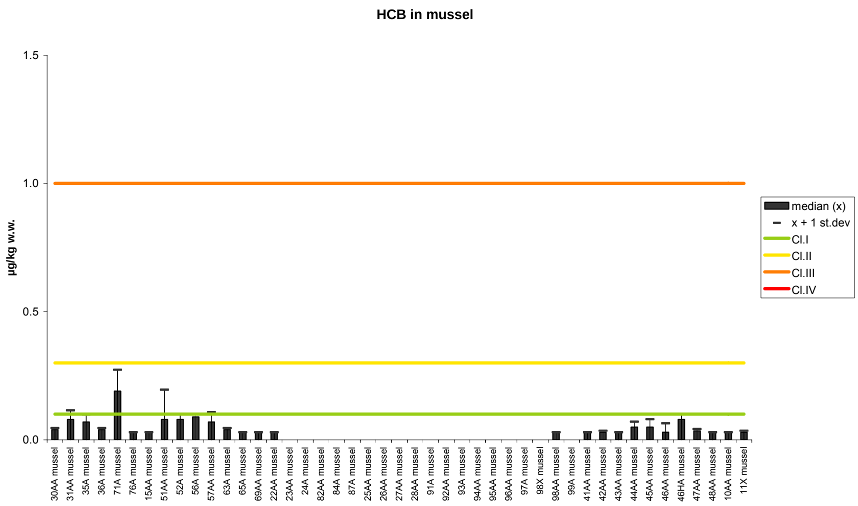


Figure 33. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for HCB in blue mussel (*Mytilus edulis*) 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight (see maps in Appendix G).

A

B

C

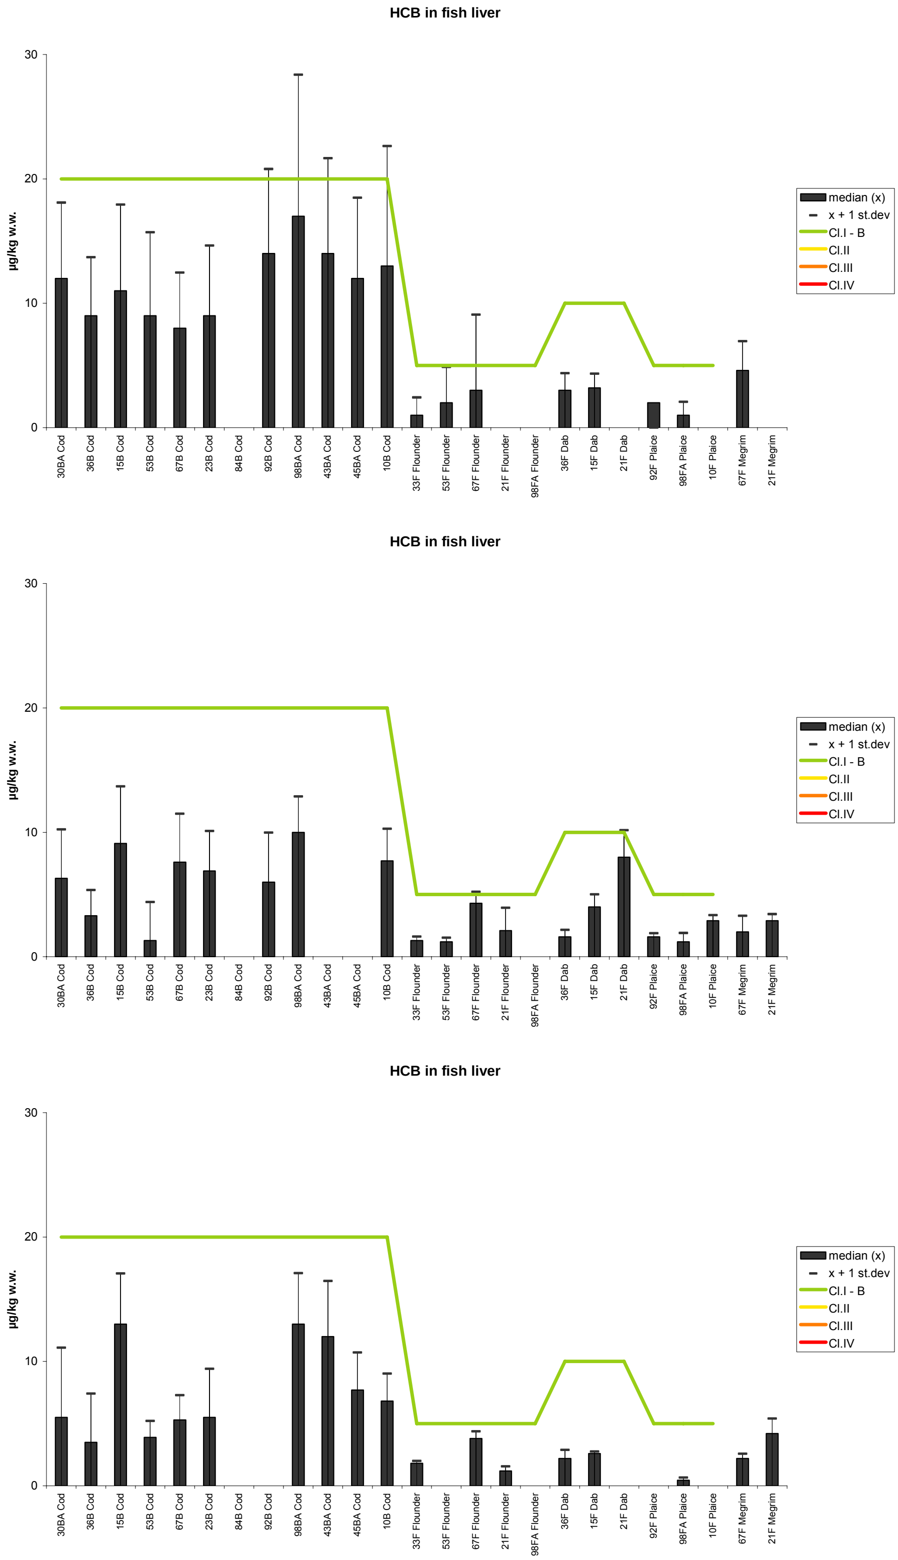

Figure 34. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for HCB in fish liver 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppb (µg/kg) wet weight, "Cl. – B" indicates that only upper limit to SFT Classes or provisional high back ground concentration is indicated for all fish, (see maps in Appendix G).

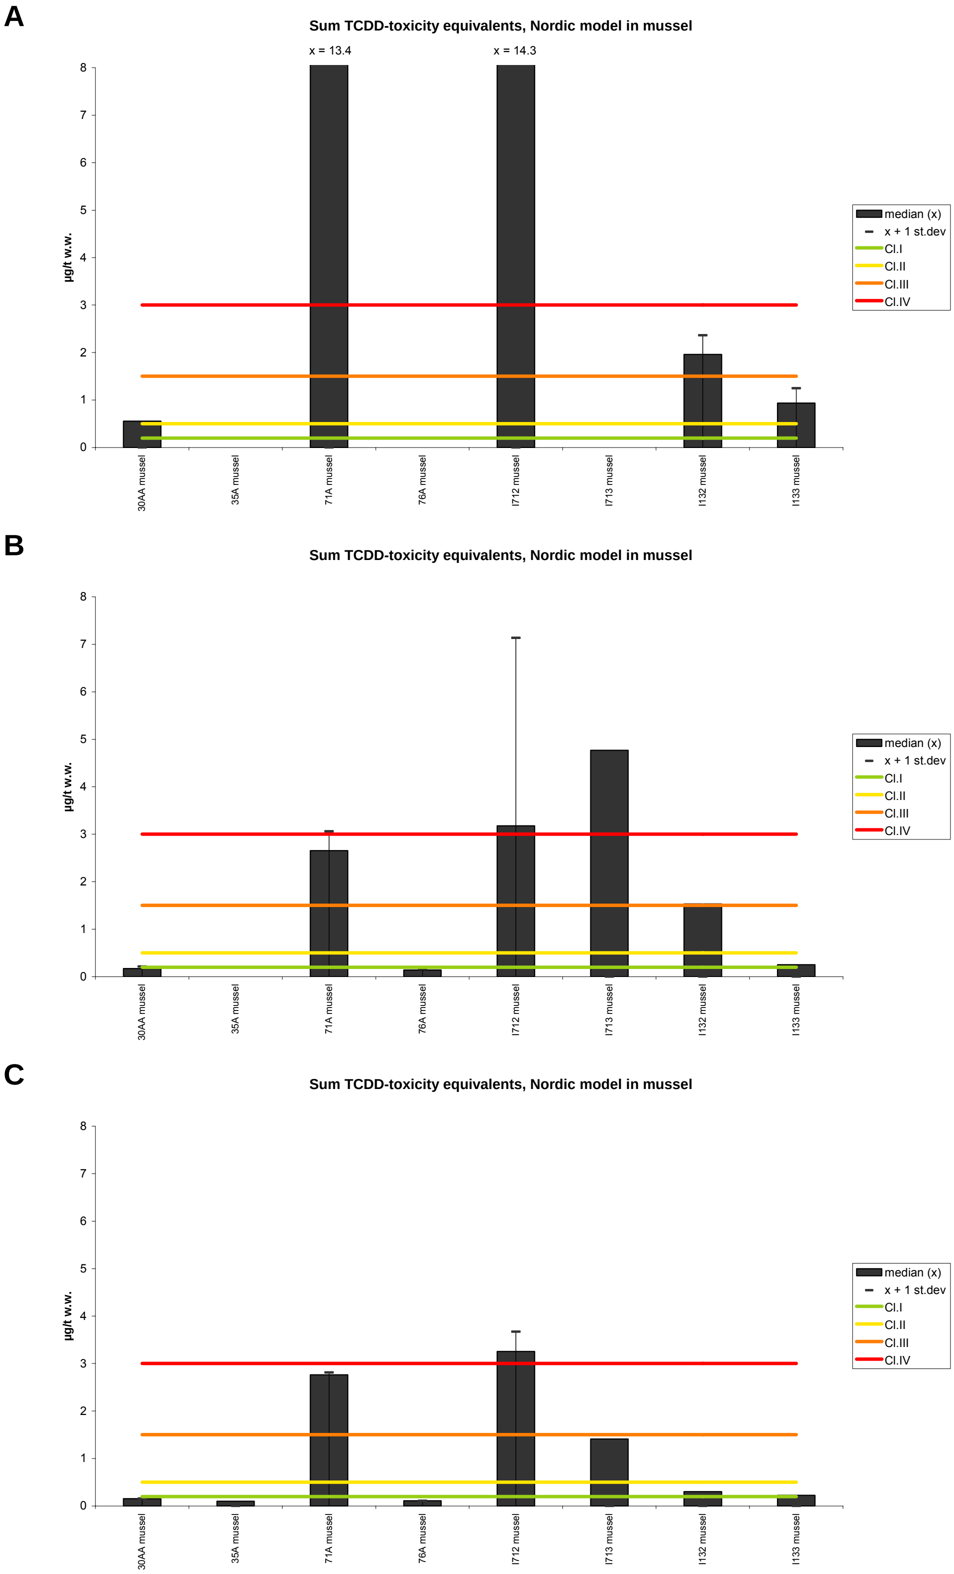

Figure 35. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for dioxin TCDD-toxicity equivalents after nordic model (TCDDN) in blue mussel 1990-1996 (**A**), 2005 (**B**) and 2006 (**C**), ppp (ng/kg) wet weight (see maps in Appendix G). NB: TCDDN is a sum of specific dioxin compounds of which may include compounds of uncertain quantification.

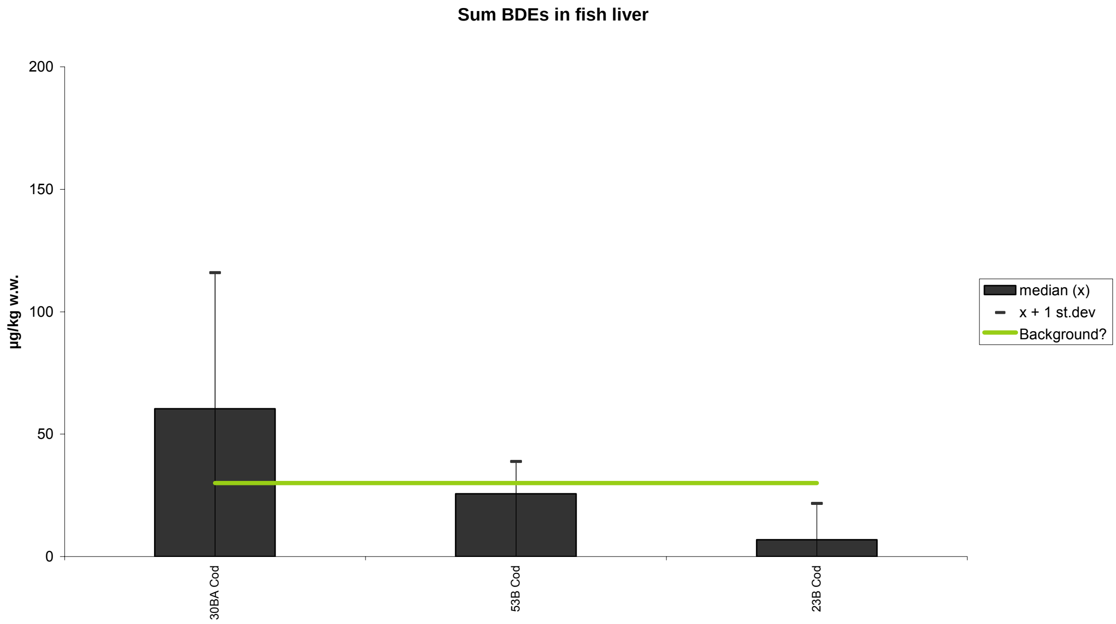
A



B

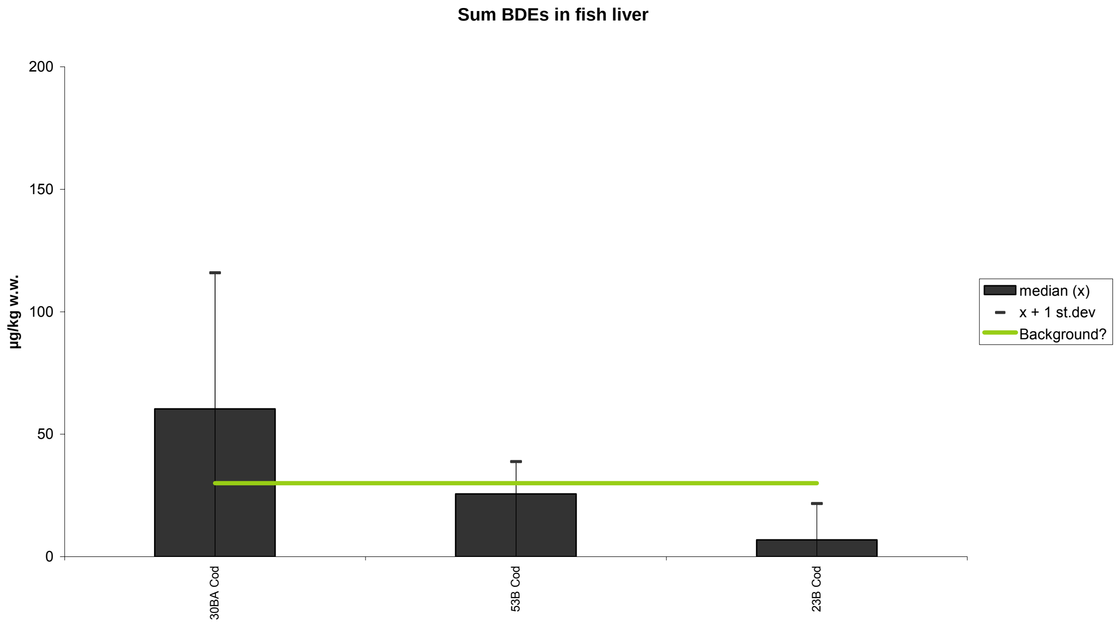


Figure 36. Median and upper limit to SFT Classes or provisional "high background" concentration for brominated flame retardent in cod liver 2005 (**A**) and 2006 (**B**) ppb (µg/kg) wet weight for three JAMP stations (inner Oslofjord - st.30B, inner Sørfjord - st.53B and Karihavet - st.23B) (see maps in Appendix G), and from two other investigations (see text).

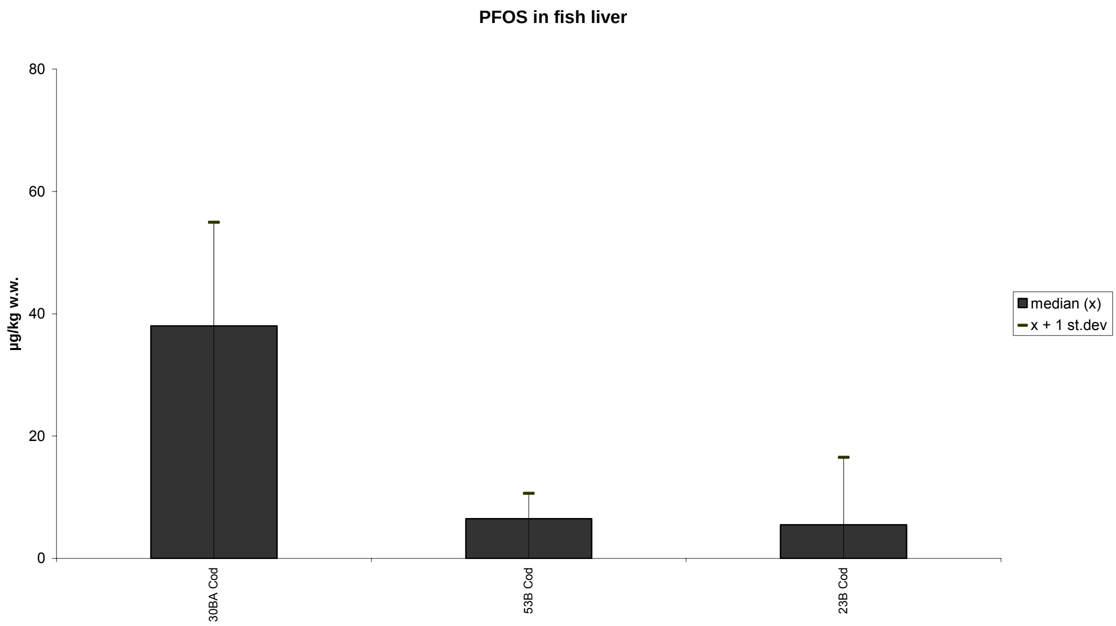
A



B

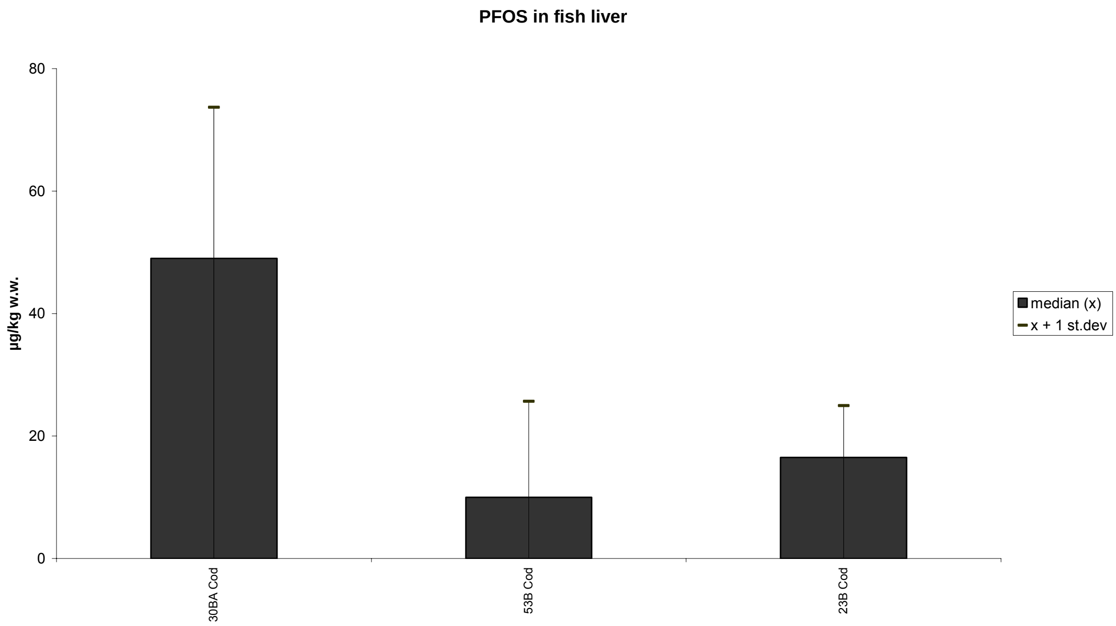


Figure 37. Median concentration for perfluoroctanoic sulfonate (PFOS) in cod liver 2005 (**A**) and 2006 (**B**) ppb (µg/kg) wet weight for three JAMP stations (inner Oslofjord - st.30B, inner Sørfjord - st.53B and Karihavet - st.23B) (see maps in Appendix G), and from two other investigations (see text).

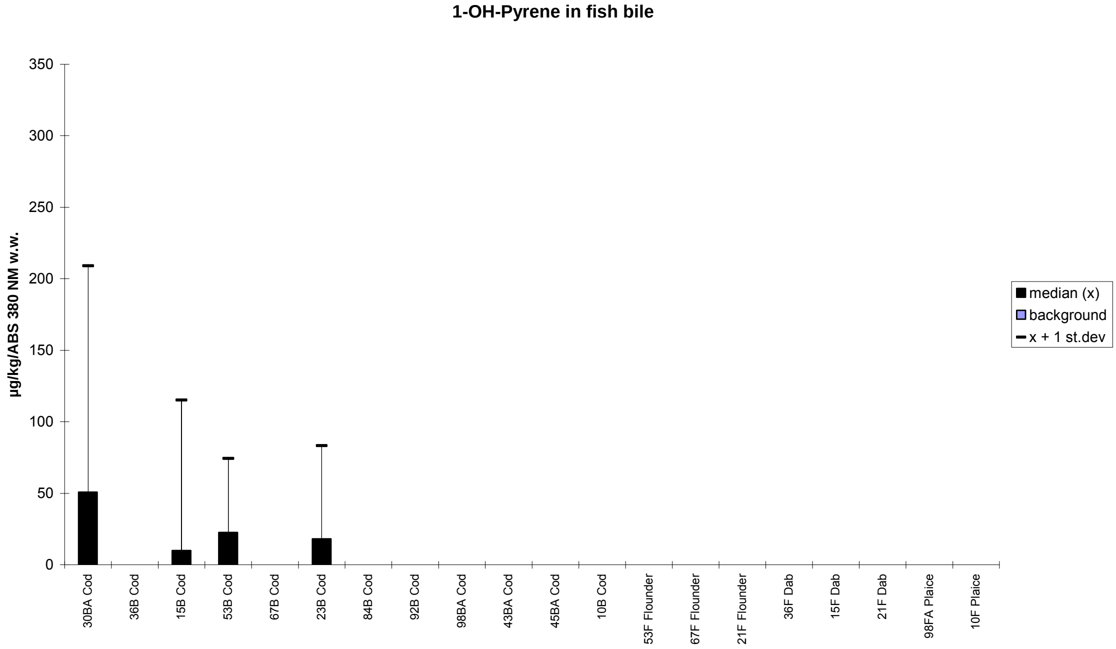
A



B

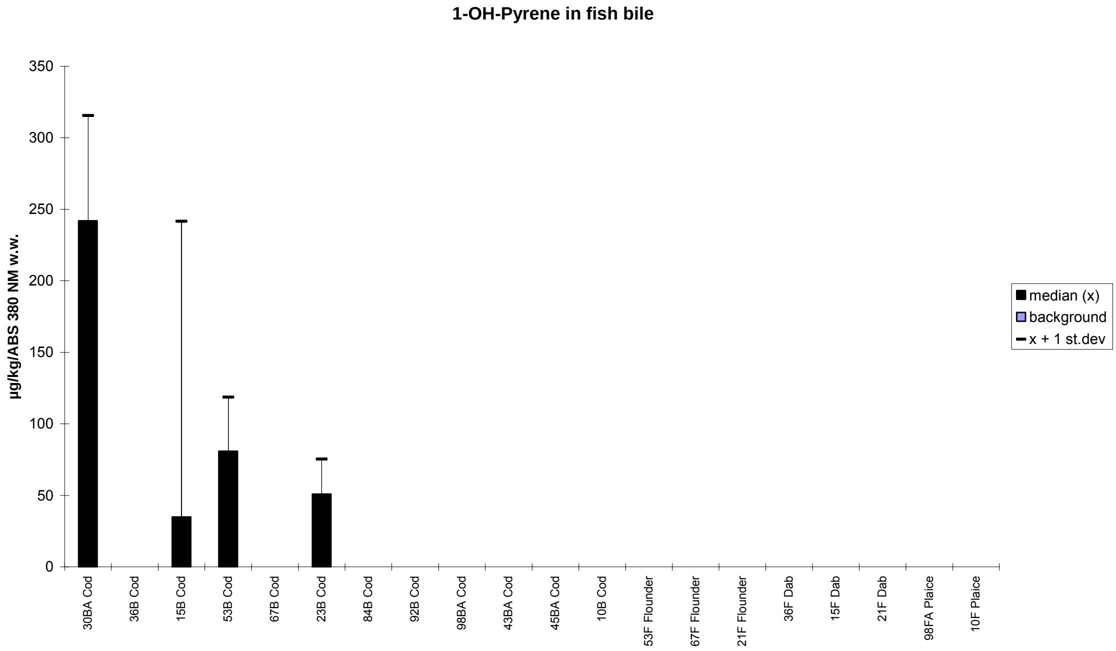


Figure 38. Median and standard deviation concentration for OH-pyrene (Pyrene metabolite) in fish bile 2005 (**A**) and 2006 (**B**), µg/kg/ABS (absorbance) 380 nm (see maps in Appendix G).

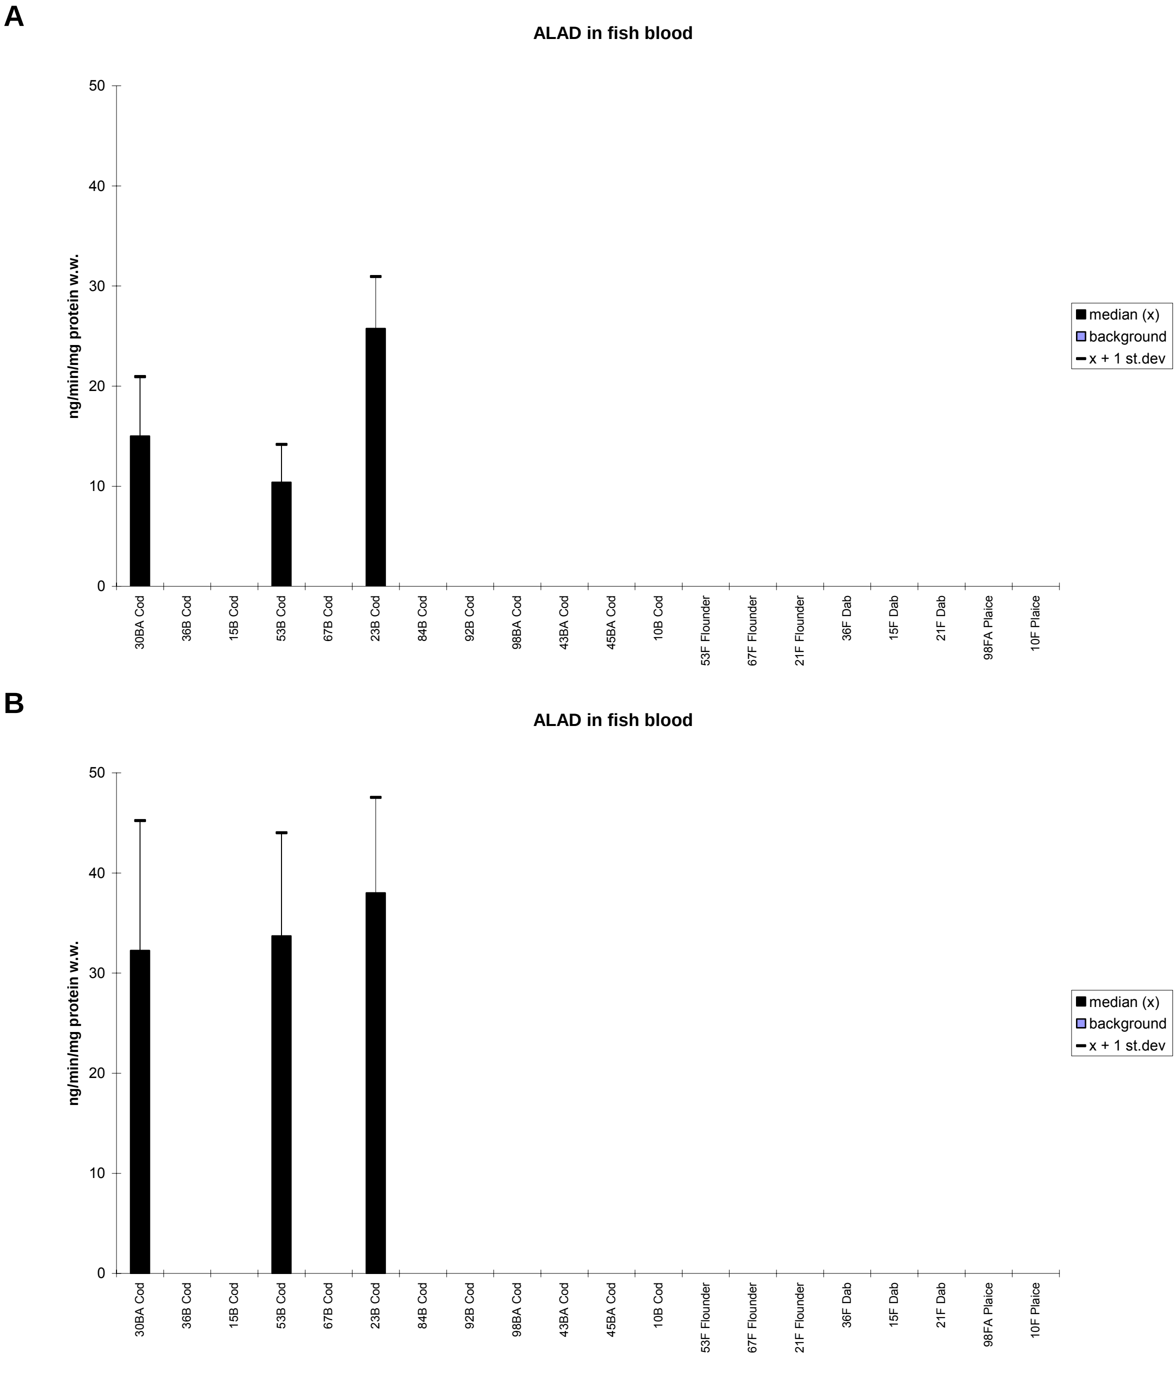

Figure 39. Median and standard deviation activity for ALA-D (δ-amino levulinic acid dehydrase inhibition) in fish liver 2005 (**A**) and 2006 (**B**), ng PBG (porphobilinogen)/min/mg protein (see maps in Appendix G).

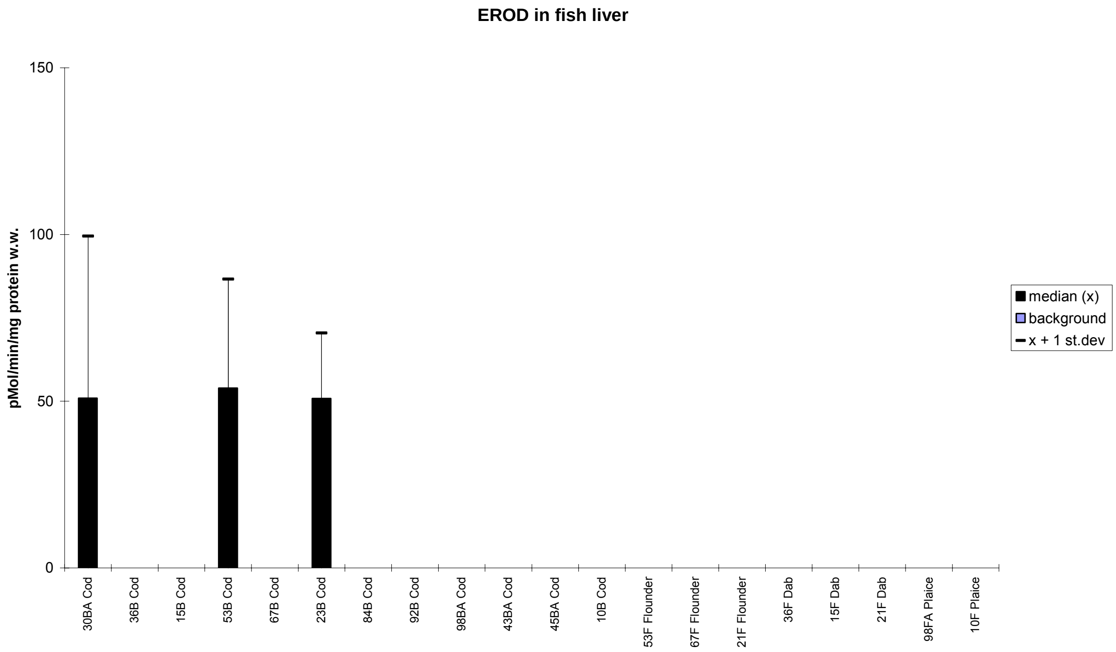
A



B

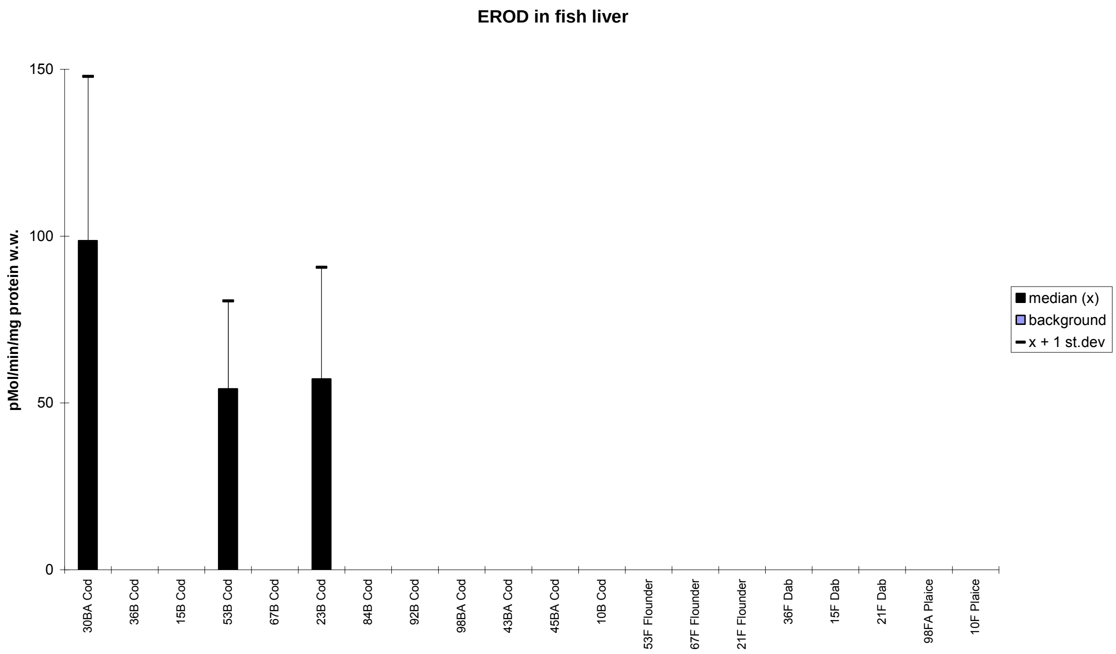


Figure 40. Median and standard deviation activity for EROD (Cytochrome P4501A-activity) in fish liver 2005 (**A**) and 2006 (**B**), pmol/min/mg protein (see maps in Appendix G).

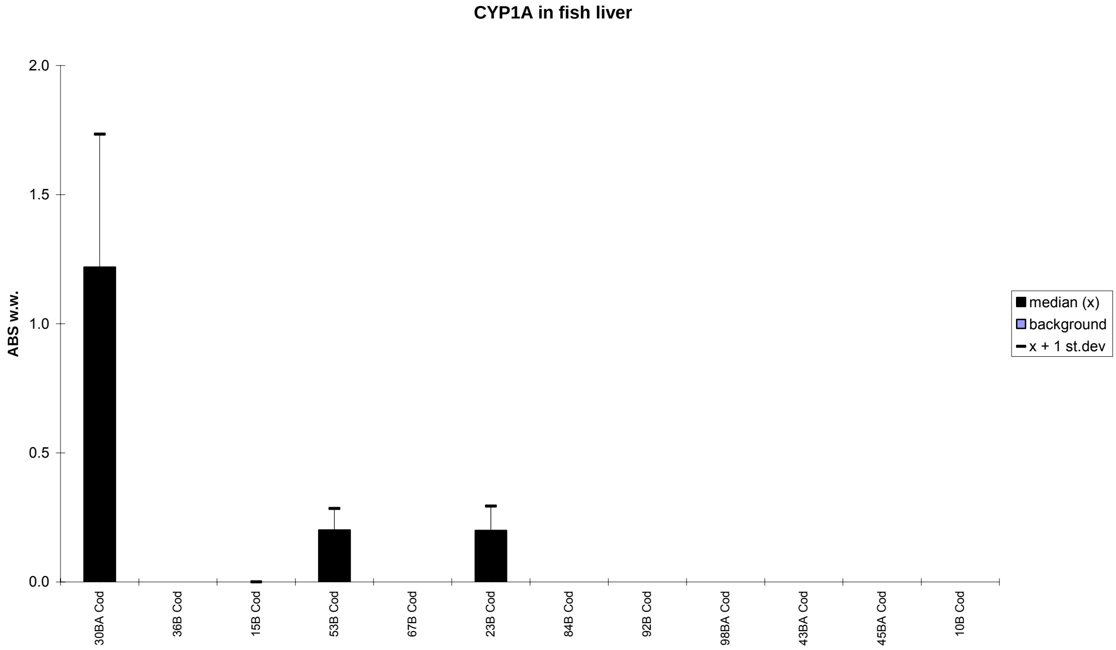
A



B

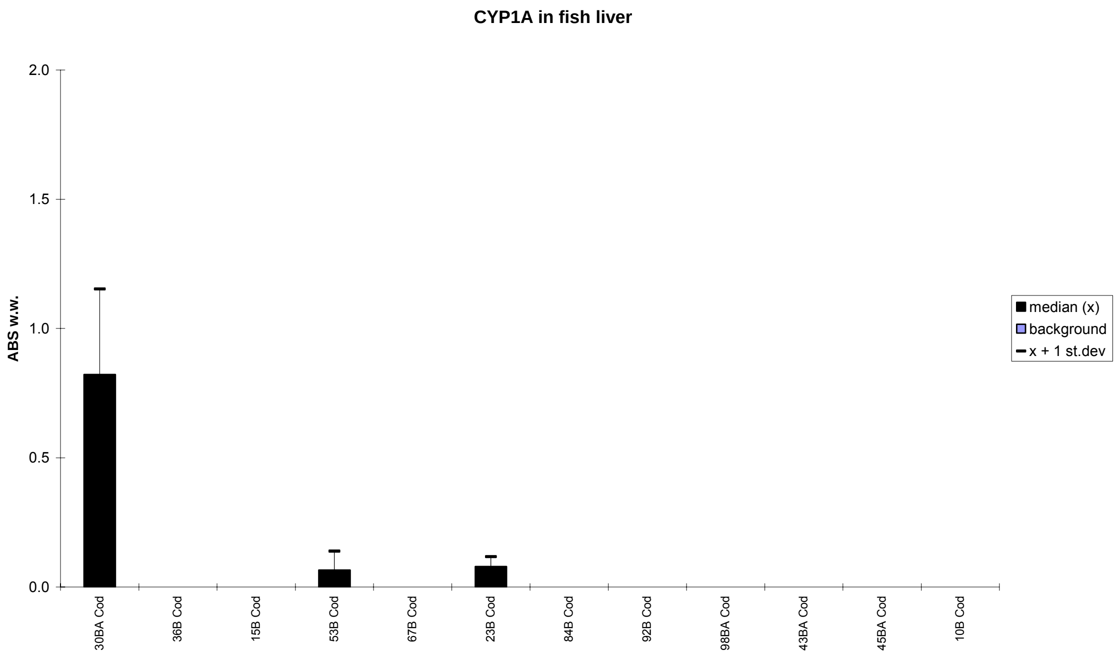


Figure 41. Median and standard deviation activity for CYP1A (relative amount of Cytochrome P4501A-protein) in fish liver 2005 (**A**) and 2006 (**B**), pmol/min/mg protein (see maps in Appendix G).

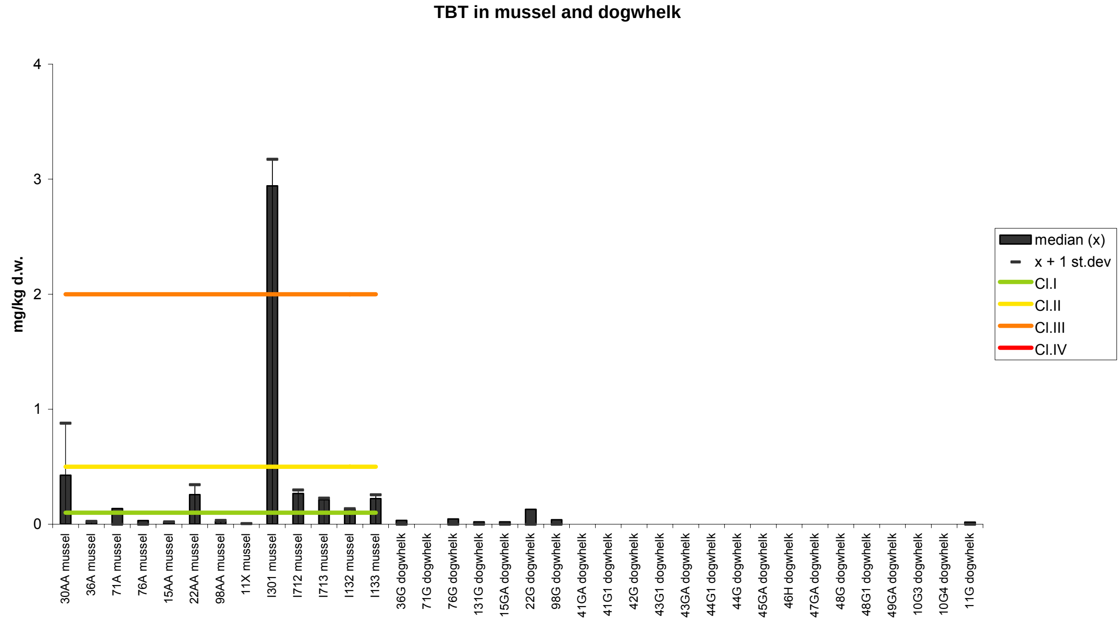
A



B

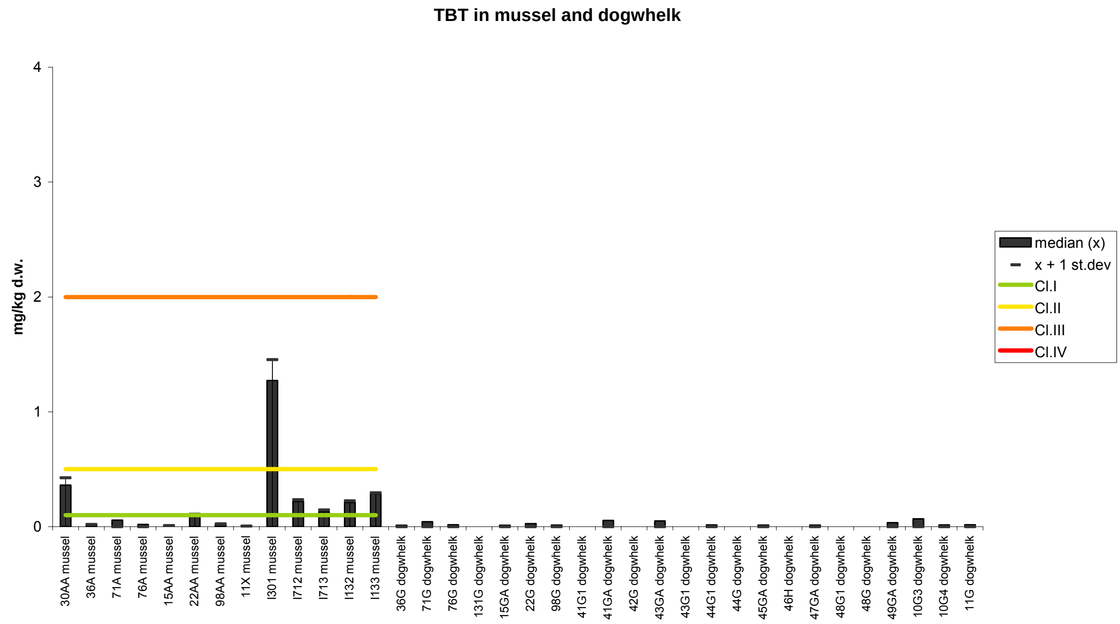


Figure 42. Median, standard deviation and upper limit to SFT Classes or provisional "high background" concentration for tributyl tin (TBT-concentration on a formulation basis) in blue mussel and dogwhelk 2005 (**A**) and 2006 (**B**), ppm (2.44* mg Sn/kg) dry weight (see maps in Appendix G).

Appendix L
Results from INDEX determinations 1995-2005

Introduction

The Norwegian Pollution Control Authority (SFT) has requested that a small group of indices be established to assess the quality of the environment with respect to contaminants. The target indicator medium for both indices may vary depending on what purpose is defined, however sediment, cod and blue mussel are considered to be the most relevant choices. Blue mussel was selected for this investigation (Appendix L1).

Two indices are calculated. One index is based on the contaminant concentrations in the blue mussel collected annually from 9 of the more contaminated fjords in Norway (Walday *et al*. 1995), herein designated "Pollution Index". This index was initiated in 1995. Initially there were 11 fjords but sampling from Orkdalsfjord and Iddefjord was discontinued in 1997. It was practical to organise sampling within JAMP. Some JAMP results could be used to calculate the index value.

In addition, a "Reference Index" was initiated in 1995 based on annual contaminant concentrations in the blue mussel. The blue mussel were collected at JAMP stations along the entire coast where there is presumably low levels of contamination. The importance of "reference" stations for monitoring of contaminants has been discussed earlier (cf. Green 1987). One of the main reasons for this work is to establish points of reference for contaminated fjords. Initially 8 areas were involved but since 1998 only 5 have been sampled.

Calculation of the index

Sampling strategy and a detailed discussion of calculation of the Pollution Index has been given earlier (cf. Walday *et al.* 1995) and only a brief summary will be given here. The relevant contaminants for each of the Pollution Index fjords are summarised in Appendix L2 and J3. Their selection is based on earlier investigations. Two to five stations were sampled from each area. Three replicate samples with 20 individuals with a shell length of 3-5 cm were collected from each station. Each sample was analysed for the contaminants according to the scheme in Appendix L2. "Dioxins" were only investigated in 1995-96, but reinstated for some stations in 2002 as part of the annual investigations. Assessment of TBT concentrations was introduced in 2002 even though it is not identified as a selection criteria by Walday *et al.* (1995).

One to three stations were sampled from selected areas for the determination of the Reference Index. Each station included three replicates which were analysed for the usual JAMP contaminants (cf. analysis code A, Appendix L2). Some samples were also analysed for PAHs and dioxins.

The strategy for sampling blue mussel differed depending on whether the blue mussel were to be used for the Index or for JAMP and Index in that stations that were exclusively to be used for Index calculations allowed a slightly greater size range (3-5 cm) compared to JAMP and that the blue mussel were frozen directly and not depurated.

The maximum median for each contaminant for all the stations in an area was determined. These concentrations were classified according to SFT's classification system for contaminants in the marine environment (Appendix L4 and Appendix L5). The highest class found for any contaminant measured in an area determined the index value for that area.

The SFT Classes are based on the provisional "high background" levels. This system has been revised (Molvær *et al.* 1997); where among other changes the sum of CB-28, -52, -101, -118, -138, -153, and -180 (CBΣΣe) is now a distinct parameter for classification. The sum of all PAHs excluding the dicyclic PAHs (PAH_Σ) was compared to the system's "sum-PAH". Previously this was the calculation of sum-PAH that included the dicyclic PAHs. As analytical methods improved through the years more non-dicyclic PAHs could be quantified, and included the C1-, C2-, and C3-dibenzpthiophenes, and C1-, C2-, C3- and methylated phenathrenes. These were included in the sum of all non-dicyclic PAHs, and comparison between years could be misleading. For this report, PAH_Σ was re-calculated, also for previous years, using only the 15 non-dycyclic PAH listed in the EPA protocol 8310[1]. The recalculation revealed only one difference from previously reported index values, and that was for the Reference Index 2006 reported to SFT as 1.6 in June of 2007, but the recalulation was 1.4 because PAH_Σ at Lista dropped into Cl.I from Cl.II.

"Dioxins" were assessed based on toxicity equivalency factors (TEQ) according to a Nordic model (Ahlborg 1989) which differs insignificantly from the recently revised WHO-model (van den Berg *et al.* 1998). Note that EPOCl is considered a relevant contaminant for one area but is not included in the part of the classification system based on levels in blue mussel. Likewise, there are contaminants which are included in the classification system but have not been measured in any area (e.g., tributyltin (TBT), arsenic, fluoride, nickel, silver).

The maximum class found for any contaminant determined the Class (I-V) of the area. The average Class for all the contaminated sub areas and all the reference localities determined the Pollution or Reference Index, respectively. The lowest Index value is 1 and means that all median values were in Class I (insignificantly polluted). The highest Index value is 5 and means that at least one median value from each of the areas was in Class V (extremely polluted).

Conclusion from application of the indices

The indices have been in use since 1995 based on contaminant concentrations in blue mussel from 14-19 areas (cf. Green *et al.* 2007). An assessment of their application suggested that the pollution index needed mainly two improvements (Green & Knutzen 2001): 1) more stations to avoid the consequences of insufficient sample size and 2) inclusion of more relevant contaminant analyses with respect to the pollution load expected and in relation to the SFT classification system for environmental quality (Molvær *et al.* 1997). SFT provided funds to improve the index in 2002. Three additional stations have since been established: one in the Frierfjord area (I713 Strømtangen, about 800 m east of I711 Steinsholmen), one in the inner Ranfjord (I964 Toraneskaien, about 500 m north of I965 Moholmen) and one in the Sunndalsfjord area (I915 Flåøya, northwest, about halfway between I913 and the inner most part of the fjord). Dioxin and TBT analyses were added to the programme for samples collected in the Frierfjord area, inner Oslofjord and the inner Kristiansandsfjord. TBT-analyses were also included for some of the reference stations (see Annex). These changes affect the outcome of the index and comparison to previous years should be cautioned. For results up to and including 2001 SFT has presented only the results using the old method of calculation, for 2002 the results for both the old and new methods are presented, and for 2003 and since then only the results for the new method are presented (cf. SFT's website at www.miljostatus.no/templates/themepage___2699.aspx or www.miljøstatus.no >> *Vannforurensning* >> *Miljøgifter,vann*.) Comparison of the two methods for 2002 and 2003 has been done earlier (Green *et al.*, 2004 a, b).

It should also be noted that the SFT classification system is under revision and may affect calculations of the indices in the future. One likely change will be the lowering of limits to the

[1] Acenaphthene, acenaphthylene, anthracene, benzo[*a*]anthracene, benzo[*a*]pyrene, benzo[b]fluoranthene, benzo[ghi]perlyene, benzo[*k*]fluoranthene, chrysene, dibenzo[*a,h*]anthracene, fluoranthene, indeno[*1,2,3-cd*]pyrene, phenanthrene and pyrene. NB. for NIVA's PAH_Σ, a where these cannot be distinguished but included in a group, such as benzo[*b*]fluoranthene benzo[*b,b,f*]fluoranthene, the value for the group is used. A single compound can not be included in more than one group.

classes for PCBs taking into consideration a lower background from 4 to 3 ppb wet weight suggested by Green & Knutzen (2003).

No special considerations were made when one but not all the stations within an area were sampled. The lack of sufficient samples has occurred several times for the Pollution Index: (st. I205 Bølsnes from Saudafjord 1996, st. I911 Horvika in the Sunndalsfjord since 1999, st. I021 in the Hvaler area 1999, st.I962 in the Inner Ranfjord since 1999, and st. I711 Steinholmen in the Frierfjord 2001).

Because insufficient amount of blue mussel were found at station Horvika in the Sunndalsfjord, two new stations were introduced; Fjøseid (I913) in 1999 and Flåøya, northwest (I915), in 2003, about 15 and 5 km farther out the fjord from Horvika, respectively. It can be noted that inclusion of supplementary analyses of blue mussel from the “Hydro kai” (I916), innermost in Sunndalsfjord, would have increased the index. Because sufficient amount of blue mussel were not found at station I962 Koksverktomta in the Ranfjord since 1999, a new station (I965 - Moholmen) was introduced in 2001 about 2 km south of Koksverktomta.

Based on the new calculation with the mentioned supplementary stations and supplementary analyses of dioxin and TBT, the **Pollution Index for 2006 was 2.9** compared to 3.1 for 2005 (Table 10, Appendix L4). A value between 3 and 4 would be between “Marked” and “Severe” Classes in the SFT system, and between 2 and 3 would be between “Moderate” and “Marked” Classes. The index decreased one class for both Inner Oslofjord, Kristiansandsfjord and Sørfjorden, because of lower concentrations of TBT, dioxins and lead, respectively, but increased one class for Inner Ranfjord because of benzo[*a*]pyrene. Statistical analyses did reveal significant temporal trends but only a downward trend was found for TBT from the Inner Oslofjord in this group of combination contaminant/fjords.

Only 5 fjords/areas were monitored for the Reference Index for 1998-2006 compared to 7 for 1997 and 8 for 1995-1996 (Table 11, Appendix L5). However, only four of these provided a common basis (cf., Table 11). Similar to the application Pollution Index, the Reference Index made no special considerations when one but not all the stations within an area were sampled. For the four common areas, this has occurred several times, all in the Varangerfjord area (st.48A since 1997 and st.11A since 1998). With Lofoten and the supplementary analyses of TBT included, the **Reference Index for 2006 was 1.4**, unchanged from 2005 (Table 11, Appendix L5). All five fjords/areas included the TBT analyses. A value between 1 and 2 would be between “Slight” and “Moderate” Classes. The index increased one class for the mid/outer Oslofjorden because of an increase in DDT. No statistically significant temporal trends were found for DDT from stations in these fjords/areas.

Table 10. Maximum environmental classification for fjords selected for Pollution INDEX. (See text and Appendix L4).

* - JAMP station but not sampled in accordance to JAMP guidelines, see Appendix text.
** - Sufficient mussel-sample not found in 1996.

Notes (CM):
- a - blue mussel collected from buoy and/or buoy anchor lines
- b - blue mussel collected from sand/gravel bottom
- c - blue mussel collected from iron/cement pilings
- d - blue mussel collected from metal navigation buoys
- e - blue mussel collected from floating dock
- f - blue mussel collected from wooden docks
- g - blue mussel collected from tire on jetty

Appendix L2
INDEX - Key to analysis codes and sample counts
(Used in Appendix L1)

ANALYSIS CODES[1)] See Walday *et al.* (1995) for discussion of selection of analyses.

Contaminant	Analysis code

[1]) Concerns MUSSEL - 1 size group (3-5 cm), 3 replicate samples each a bulk of 20 individuals (see text)
[2]) Concerns MUSSEL - discontinued since 1996
[3]) Concerns MUSSEL - discontinued since 1995, but reinstated 2002 for st.30A, 71A, I711, I712, I713, 76A, I132 and I133
[4]) Concerns MUSSEL – not included in Walday *et al.* (1995).

Appendix L3
INDEX - SFT Environmental quality classes

(Molvær *et al.* 1997)

As	Arsenic
Pb	Lead
F	Fluoride
Cd	Cadmium
Cu	Copper
Cr	Chromium
Hg	Mercury
Ni	Nickel
Zn	Zinc
Ag	Silver
TBT	Tributyltin
PAH_S	total PAH excluding dicyclic (=PAH_Σ)*
BAP	benzo[*a*]pyrene
DDTSS	DDTPP+DDEPP+TDEPP (=DDTΣΣ)*
HCB	hexachlorobenzene
HCHSS	HCHG+HCHA+HCHB (=HCHΣΣ)*
CBSSe	sum of CB: 28+52+101+118+138+153+180 *
TCDDN	Sum of TCDD-toxicity equivalents *

*) See also Appendix B for definitions.

Basis: D = dry weight, W = wet weight
Units: M = ppm (mg/kg), U = ppb (µg/kg), P = ppp (ng/kg)

SFT's Environmental quality classes for blue mussel (Molvær *et al.* 1997).

Contaminant	basis	unit	Class I	Class II	Class III	Class IV	Class V
As	D	M	<10	10-30	30-100	100-200	>200

Statens forurensningstilsyn
Postboks 8100 Dep,
0032 Oslo
Besøksadresse: Strømsveien 96

Telefon: 22 57 34 00
Telefaks: 22 67 67 06
E-post: postmottak@sft.no
www.sft.no

Statlig program for forurensningsovervåking omfatter overvåking av forurensningsforholdene i luft og nedbør, skog, vassdrag, fjorder og havområder. Overvåkningsprogrammet dekker langsiktige undersøkelser av:

- overgjødsling
- forsuring (sur nedbør)
- ozon (ved bakken og i stratosfæren)
- klimagasser
- miljøgifter

Overvåkningsprogrammmet skal gi informasjon om tilstanden og utviklingen av forurensningssituasjonen, og påvise eventuell uheldig utvikling på et tidlig tidspunkt. Programmet skal dekke myndighetenes informasjonsbehov om forurensningsforholdene, registrere virkningen av iverksatte tiltak for å redusere forurensningen, og danne grunnlag for vurdering av nye tiltak. SFT er ansvarlig for gjennomføringen av overvåkningsprogrammet
